

Package ‘r2glmm’

April 28, 2025

Type Package

Title Computes R Squared for Mixed (Multilevel) Models

Date 2025-04-28

Version 0.1.3

Description The model R squared and semi-partial R squared for the linear and generalized linear mixed model (LMM and GLMM) are computed with confidence limits. The R squared measure from Edwards et.al (2008) <[DOI:10.1002/sim.3429](https://doi.org/10.1002/sim.3429)> is extended to the GLMM using penalized quasi-likelihood (PQL) estimation (see Jaeger et al. 2016 <[DOI:10.1080/02664763.2016.1193725](https://doi.org/10.1080/02664763.2016.1193725)>). Three methods of computation are provided and described as follows. First, The Kenward-Roger approach. Due to some inconsistency between the 'pbkrtest' package and the 'glmmPQL' function, the Kenward-Roger approach in the 'r2glmm' package is limited to the LMM. Second, The method introduced by Nakagawa and Schielzeth (2013) <[DOI:10.1111/j.2041-210x.2012.00261.x](https://doi.org/10.1111/j.2041-210x.2012.00261.x)> and later extended by Johnson (2014) <[DOI:10.1111/2041-210X.12225](https://doi.org/10.1111/2041-210X.12225)>. The 'r2glmm' package only computes marginal R squared for the LMM and does not generalize the statistic to the GLMM; however, confidence limits and semi-partial R squared for fixed effects are useful additions. Lastly, an approach using standardized generalized variance (SGV) can be used for covariance model selection. Package installation instructions can be found in the readme file.

Imports mgcv, Matrix, pbkrtest, ggplot2, afex, stats, MASS, gridExtra, grid

Suggests lme4, nlme, testthat, data.table, dplyr, lmerTest

calc_sgv	<i>Compute the standardized generalized variance (SGV) of a blocked diagonal matrix.</i>
----------	--

Description

Compute the standardized generalized variance (SGV) of a blocked diagonal matrix.

Usage

```
calc_sgv(nblocks = NULL, blksizes = NULL, vmat)
```

Arguments

nblocks	Number of blocks in the matrix.
blksizes	vector of block sizes
vmat	The blocked covariance matrix

Value

The SGV of the covariance matrix vmat.

Examples

```
library(Matrix)
v1 = matrix(c(1,0.5,0.5,1), nrow = 2)
v2 = matrix(c(1,0.2,0.1,0.2,1,0.3,0.1,0.3,1), nrow = 3)
v3 = matrix(c(1,0.1,0.1,0.1,1,0.2,0.1,0.2,1), nrow = 3)
calc_sgv(nblocks = 3, blksizes = c(2,3,3), vmat = Matrix::bdiag(v1,v2,v3))
```

 cmp_R2

 Compute R2 with a specified C matrix

Description

Compute R2 with a specified C matrix

Usage

```
cmp_R2(c, x, SigHat, beta, method, obsperclust = NULL, nclusts = NULL)
```

Arguments

c	Contrast matrix for fixed effects
x	Fixed effects design matrix
SigHat	estimated model covariance (matrix or scalar)
beta	fixed effects estimates
method	the method for computing r2beta
obsperclust	number of observations per cluster (i.e. subject)
nclusts	number of clusters (i.e. subjects)

Value

A vector with the Wald statistic (ncp), approximate Wald F statistic (F), numerator degrees of freedom (v1), denominator degrees of freedom (v2), and the specified r squared value (Rsq)

Examples

```
library(nlme)
library(lme4)
library(mgcv)
lmemod = lme(distance ~ age*Sex, random = ~1|Subject, data = Orthodont)
X = model.matrix(lmemod, data = Orthodont)
SigHat = extract.lme.cov(lmemod, data = Orthodont)
beta = fixef(lmemod)
p = length(beta)
obsperclust = as.numeric(table(lmemod$data[, 'Subject']))
nclusts = length(obsperclust)
C = cbind(rep(0, p-1), diag(p-1))
partial.c = make.partial.C(p-1, p, 2)

cmp_R2(c=C, x=X, SigHat=SigHat, beta=beta, obsperclust = obsperclust,
nclusts = nclusts, method = 'sgv')
cmp_R2(c=partial.c, x=X, SigHat=SigHat, beta=beta, obsperclust = obsperclust,
nclusts = nclusts, method = 'sgv')
```

glmPQL	<i>Compute PQL estimates for fixed effects from a generalized linear model.</i>
--------	---

Description

Compute PQL estimates for fixed effects from a generalized linear model.

Usage

```
glmPQL(glm.mod, niter = 20, data = NULL)
```

Arguments

glm.mod	a generalized linear model fitted with the glm function.
niter	maximum number of iterations allowed in the PQL algorithm.
data	The data used by the fitted model. This argument is required for models with special expressions in their formula, such as offset, log, cbind(sucesses, trials), etc.

Value

A glmPQL object (i.e. a linear model using pseudo outcomes).

Examples

```
# Load the datasets package for example code
library(datasets)
library(dplyr)

# We'll model the number of world changing discoveries per year for the
# last 100 years as a poisson outcome. First, we set up the data

dat = data.frame(discoveries) %>% mutate(year = 1:length(discoveries))

# Fit the GLM with a poisson link function
mod <- glm(discoveries~year+I(year^2), family = 'poisson', data = dat)

# Find PQL estimates using the original GLM
mod.pql = glmPQL(mod)

# Note that the PQL model yields a higher R Squared statistic
# than the fit of a strictly linear model. This is attributed
# to correctly modelling the distribution of outcomes and then
# linearizing the model to measure goodness of fit, rather than
# simply fitting a linear model

summary(mod.pql)
summary(linfit <- lm(discoveries~year+I(year^2), data = dat))
```

```
r2beta(mod.pql)
r2beta(linfit)
```

is.CompSym *Checks if a matrix is Compound Symmetric.*

Description

Checks if a matrix is Compound Symmetric.

Usage

```
is.CompSym(mat, tol = 1e-05)
```

Arguments

mat	The matrix to be tested.
tol	a number indicating the smallest acceptable difference between off diagonal values.

Value

True if the matrix is compound symmetric.

Examples

```
gcmat <- matrix(c(1,0.2,0.1,0.2,1,0.3,0.1,0.3,1), nrow = 3)
csmat <- matrix(c(1,0.2,0.2,0.2,1,0.2,0.2,0.2,1), nrow = 3)
is.CompSym(csmat)
```

make.partial.C *Generate partial contrast matrices*

Description

Generate partial contrast matrices

Usage

```
make.partial.C(rows, cols, index)
```

Arguments

rows	Number of rows in the contrast matrix
cols	Number of columns in the contrast matrix
index	A number corresponding to the position of the fixed effect in the vector of fixed effect parameter estimates.

Value

A contrast matrix designed to test the fixed effect corresponding to index in the vector of fixed effects.

Examples

```
make.partial.C(4, 5, 2)
make.partial.C(4, 5, 3)
make.partial.C(4, 5, 2:4)
```

plot.R2

Visualize standardized effect sizes and model R squared

Description

Visualize standardized effect sizes and model R squared

Usage

```
## S3 method for class 'R2'
plot(
  x,
  y = NULL,
  txtsize = 10,
  maxcov = 3,
  r2labs = NULL,
  r2mthd = "sgv",
  cor = TRUE,
  ...
)
```

Arguments

x	An R2 object from the r2beta function.
y	An R2 object from the r2beta function.
txtsize	The text size of the axis labels.
maxcov	Maximum number of covariates to include in the semi-partial plots.
r2labs	a character vector containing labels for the models. The labels are printed as subscripts on a covariance model matrix.

r2mthd	The method used to compute R2
cor	An argument to be passed to the r2dt function. Only relevant if comparing two R2 objects.
...	Arguments to be passed to plot

Value

A visual representation of the model and semi-partial R squared from the r2 object provided.

Examples

```
library(nlme)
library(r2glmm)

data(Orthodont)

# Linear mixed model
lmemod = lme(distance ~ age*Sex, random = ~1|Subject, data = Orthodont)

r2 = r2beta(model=lmemod,partial=TRUE,method='sgv')

plot(x=r2)
```

pqlmer

pqlmer

Description

Fit a GLMM model with multivariate normal random effects using Penalized Quasi-Likelihood for mermod objects.

Usage

```
pqlmer(formula, family, data, niter = 40, verbose = T)
```

Arguments

formula	The lme4 model formula.
family	a family function of the error distribution and link function to be used in the model.
data	the dataframe containing the variables in the model.
niter	Maximum number of iterations to perform.
verbose	if TRUE, iterations are printed to console.

Value

A pseudo linear mixed model of class "lme" .

See Also[glmPQL](#)**Examples**

```
# Compare lmer PQL with lme PQL

library(MASS)

lmePQL = glmPQL(y ~ trt + week + I(week > 2), random = ~ 1 | ID,
               family = binomial, data = bacteria,
               verbose = FALSE)

merPQL= pqlmer(y ~ trt + week + I(week > 2) + (1 | ID),
              family = binomial, data = bacteria,
              verbose = FALSE)

summary(lmePQL)
summary(merPQL)
```

print.R2

Print the contents of an R2 object

Description

Print the contents of an R2 object

Usage

```
## S3 method for class 'R2'
print(x, ...)
```

Arguments

x an object of class R2

... other arguments passed to the print function.

r2beta	<i>r2beta Compute R Squared for Mixed Models</i>
--------	--

Description

Computes coefficient of determination (R squared) from [edwards et al., 2008](#) and the generalized R squared from [Jaeger et al., 2016](#). Currently implemented for linear mixed models with [lmer](#) and [lme](#) objects. For generalized linear mixed models, only [glmmPQL](#) are supported.

Usage

```
r2beta(model, partial = TRUE, method = "sgv", data = NULL)
```

Arguments

model	a fitted mermod, lme, or glmmPQL model.
partial	if TRUE, semi-partial R squared are calculated for each fixed effect in the mixed model.
method	Specifies the method of computation for R squared beta: if method = 'sgv' then the standardized generalized variance approach is applied. This method is recommended for covariance model selection. if method = 'kr', then the Kenward Roger approach is applied. This option is only available for lme models. if method = 'nsj', then the Nakagawa and Schielzeth approach is applied. This option is available for lmer and lme objects. if method = 'lm', the classical R squared from the linear model is computed. This method should only be used on glm and lm object.
data	The data used by the fitted model. This argument is required for models with special expressions in their formula, such as <code>offset</code> , <code>log</code> , <code>cbind(succeses, trials)</code> , etc.

Value

A dataframe containing the model F statistic, numerator and denominator degrees of freedom, non-centrality parameter, and R squared statistic with 95 percent confidence limits. If `partial = TRUE`, then the dataframe also contains partial R squared statistics for all fixed effects in the model.

Examples

```

library(nlme)
library(lme4)
data(Orthodont)

# Linear mixed models
mermod = lmer(distance ~ age*Sex + (1|Subject), data = Orthodont)
lmemod = lme(distance ~ age*Sex, random = ~1|Subject, data = Orthodont)

# The Kenward-Roger approach
r2beta(mermod, method = 'kr')

# Standardized Generalized Variance
r2beta(mermod, method = 'sgv')
r2beta(lmemod, method = 'sgv')

# The marginal R squared by Nakagawa and Schielzeth (extended by Johnson)
r2beta(mermod, method = 'nsj')

# linear and generalized linear models

library(datasets)
dis = data.frame(discoveries)
dis$year = 1:nrow(dis)

lmod = lm(discoveries ~ year + I(year^2), data = dis)
glmod = glm(discoveries ~ year + I(year^2), family = 'poisson', data = dis)

# Using an inappropriate link function (normal) leads to
# a poor fit relative to the poisson link function.

r2beta(lmod)
r2beta(glmod)

# PQL models
# Currently only SGV method is supported
library(MASS)
PQL_bac = glmmPQL(y ~ trt + I(week > 2), random = ~ 1 | ID,
                  family = binomial, data = bacteria,
                  verbose = FALSE)

r2beta(PQL_bac, method='sgv')

```

r2dt

R Squared Difference Test (R2DT). Test for a statistically significant difference in generalized explained variance between two candidate models.

Description

R Squared Difference Test (R2DT). Test for a statistically significant difference in generalized explained variance between two candidate models.

Usage

```
r2dt(
  x,
  y = NULL,
  cor = TRUE,
  fancy = FALSE,
  onesided = TRUE,
  clim = 95,
  nsims = 2000,
  mu = NULL
)
```

Arguments

x	An R2 object from the r2beta function.
y	An R2 object from the r2beta function. If y is not specified, Ho: $E[x] = \mu$ is tested (μ is specified by the user).
cor	if TRUE, the R squared statistics are assumed to be positively correlated and a simulation based approach is used. If FALSE, the R squared are assumed independent and the difference of independent beta distributions is used. This only needs to be specified when two R squared measures are being considered.
fancy	if TRUE, the output values are rounded and changed to characters.
onesided	if TRUE, the alternative hypothesis is that one model explains a larger proportion of generalized variance. If false, the alternative is that the amount of generalized variance explained by the two candidate models is not equal.
clim	Desired confidence level for interval estimates regarding the difference in generalized explained variance.
nsims	number of samples to draw when simulating correlated non-central beta random variables. This parameter is only relevant if cor=TRUE.
mu	Used to test Ho: $E[x] = \mu$.

Value

A confidence interval for the difference in R Squared statistics and a p-value corresponding to the null hypothesis of no difference.

Examples

```
library(nlme)
library(lme4)
library(r2glmm)
```

```
data(Orthodont)

# Comparing two linear mixed models
m1 = lmer(distance ~ age*Sex+(1|Subject), Orthodont)
m2 = lmer(distance ~ age*Sex+(1+age|Subject), Orthodont)

m1r2 = r2beta(model=m1,partial=FALSE)
m2r2 = r2beta(model=m2,partial=FALSE)

# Accounting for correlation can make a substantial difference.

r2dt(x=m1r2, y = m2r2, cor = TRUE)
r2dt(x=m1r2, y = m2r2, cor = FALSE)
