Type Package

Title Randomized Singular Value Decomposition

Version 1.0.2

Date 2019-07-28

Author N. Benjamin Erichson [aut, cre]

Maintainer N. Benjamin Erichson <erichson@berkeley.edu>

Description Low-rank matrix decompositions are fundamental tools and widely used for data analysis, dimension reduction, and data compression. Classically, highly accurate deterministic matrix algorithms are used for this task. However, the emergence of large-scale data has severely challenged our computational ability to analyze big data. The concept of randomness has been demonstrated as an effective strategy to quickly produce approximate answers to familiar problems such as the singular value decomposition (SVD). The rsvd package provides several randomized matrix algorithms such as the randomized singular value decomposition (rsvd), randomized principal component analysis (rpca), randomized robust principal component analysis (rrpca), randomized interpolative decomposition (rid), and the randomized CUR decomposition (rcur). In addition several plot functions are provided. The methods are discussed in detail by Erichson et al. (2016) <arXiv:1608.02148>.

 digits

Digits

Description

Subsampled MNIST database of handwritten digits. This smaller dataset has 3000 samples for each of the digits corresponding to the class labels 0,1,2,3. Each 28x28 image patch is stored as a flattened row vector.

Usage

```
data('digits')
```

Format

An object of class `rsvd`.

Source

mnist¹

References

Examples

```
## Not run:
library('rsvd')
data('digits')

#Display first digit
digit <- matrix(digits[1,], nrow = 28, ncol = 28)
image(digit[,28:1], col = gray(255:0 / 255))

## End(Not run)
```

ggbiplot

*Biplot for rpca using ggplot.***Description**

Creates a pretty biplot which is showing the individual factor map overlaid by the variables factor map, i.e, plotting both the principal component scores and directions.

Usage

```
ggbiplot(rpcaObj, pcs = c(1, 2), loadings = TRUE, groups = NULL,
         alpha = 0.6, ellipse = TRUE, alpha.ellipse = 0.2,
         var_labels = TRUE, var_labels.names = NULL, ind_labels = TRUE,
         ind_labels.names = NULL)
```

Arguments

rpcaObj	Object returned by the rpca function.
pcs	Array_like. An array with two values indicating the two PCs which should be used for plotting. By default the first two PCs are used, e.g., $c(1, 2)$.
loadings	Bool (<i>TRUE</i> , <i>FALSE</i>), optional. If <i>TRUE</i> , the eigenvectors are unit scaled by the square root of the eigenvalues $W = W * \text{diag}(\text{sqrt}(\text{eigvals}))$.
groups	Factor, optional. Factor indicating groups.
alpha	Scalar, optional. Alpha transparency for scatter plot.
ellipse	Bool (<i>TRUE</i> , <i>FALSE</i>), optional. Draw a 1sd data ellipse for each group, if <i>TRUE</i> .
alpha.ellipse	Scalar, optional. Alpha transparency for ellipse.

`var_labels` Bool (*TRUE*, *FALSE*), optional.
 Plot variable names, if *TRUE*.
`var_labels.names` Array_like, optional.
 User specific labels for the individuals.
`ind_labels` Bool (*TRUE*, *FALSE*), optional.
 Plot data point names, if *TRUE*.
`ind_labels.names` Array_like, optional.
 User specific labels for data points.

ggcorplot

Variables factor map for rpca using ggplot.

Description

Creates a pretty plot which is showing the correlation of the original variable with the principal component (PCs).

Usage

```
ggcorplot(rpcaObj, pcs = c(1, 2), loadings = TRUE,
  var_labels = FALSE, var_labels.names = NULL, alpha = 1,
  top.n = NULL)
```

Arguments

`rpcaObj` Object returned by the `rpca` function.
`pcs` Array_like.
 An array with two values indicating the two PCs which should be used for plotting. By default the first two PCs are used, e.g., `c(1,2)`.
`loadings` Bool (*TRUE*, *FALSE*), optional.
 If *TRUE*, the eigenvectors are unit scaled by the square root of the eigenvalues $W = W * \text{diag}(\text{sqrt}(\text{eigvals}))$.

`var_labels` Bool (*TRUE*, *FALSE*), optional.
 Plot variable names, if *TRUE*.
`var_labels.names` Array_like, optional.
 User specific labels for the variables
`alpha` Scalar, optional.
 Alpha transparency of the arrows.
`top.n` Scalar, optional.
 Number of (most influential) variables to label with small circles.

`ggindplot` *Individual factor map for rpca using ggplot.*

Description

Creates a pretty plot which is showing the individual factor map, i.e, plotting the principal component scores.

Usage

```
ggindplot(rpcaObj, pcs = c(1, 2), groups = NULL, alpha = 0.6,
  ellipse = TRUE, alpha.ellipse = 0.2, ind_labels = TRUE,
  ind_labels.names = NULL)
```

Arguments

`rpcaObj` Object returned by the `rpca` function.
`pcs` Array_like.
 An array with two values indicating the two PCs which should be used for plotting. By default the first two PCs are used, e.g., `c(1,2)`.
`groups` Factor, optional.
 Factor indicating groups.

<code>alpha</code>	Scalar, optional. Alpha transparency for scatter plot.
<code>ellipse</code>	Bool (<i>TRUE</i> , <i>FALSE</i>), optional. Draw a 1sd data ellipse for each group, if <i>TRUE</i> .
<code>alpha.ellipse</code>	Scalar, optional. Alpha transparency for ellipse.
<code>ind_labels</code>	Bool (<i>TRUE</i> , <i>FALSE</i>), optional. Plot names for each individual point, if <i>TRUE</i> .
<code>ind_labels.names</code>	Array_like, optional. User specific labels for the individual points.

`ggscreepplot`

Pretty Screeplot

Description

Creates a pretty screeplot using `ggplot`. By default the explained variance is plotted against the number of the principal component. Alternatively the explained variance ratio, the cumulative explained variance ratio, or the eigenvalues can be plotted.

Usage

```
ggscreepplot(rpcaObj, type = c("var", "ratio", "cum", "eigenvals"))
```

Arguments

`rpcaObj` Object returned by the `rpca` function.
`type` String c('var', 'ratio', 'cum', 'eigenvals'), optional.

rcur

Randomized CUR matrix decomposition.

Description

Randomized CUR matrix decomposition.

Usage

```
rcur(A, k = NULL, p = 10, q = 0, idx_only = FALSE, rand = TRUE)
```

Arguments

A	array_like; numeric (m, n) input matrix (or data frame). If the data contain <i>NAs</i> na.omit is applied.
k	integer; target rank of the low-rank approximation, i.e., the number of columns/rows to be selected. It is required that k is smaller or equal to $\min(m, n)$.
p	integer, optional; oversampling parameter (default $p = 10$).
q	integer, optional; number of additional power iterations (default $q = 0$).
idx_only	bool, optional; if (<i>TRUE</i>), only the index set <code>C.idx</code> and <code>R.idx</code> is returned, but not the matrices <code>C</code> and <code>R</code> . This is more memory efficient, when dealing with large-scale data.
rand	bool, optional; if (<i>TRUE</i>), a probabilistic strategy is used, otherwise a deterministic algorithm is used.

Details

Algorithm for computing the CUR matrix decomposition of a rectangular (m, n) matrix A , with target rank $k \ll \min(m, n)$. The input matrix is factored as

$$A = C * U * R$$

using the `rid` decomposition. The factor matrix C is formed using actual columns of A , also called the partial column skeleton. The factor matrix R is formed using actual rows of A , also called the partial row skeleton.

If `rand = TRUE` a probabilistic strategy is used to compute the decomposition, otherwise a deterministic algorithm is used.

Value

`rcur` returns a list with class `id` containing the following components:

- C** `array_like`;
column subset $C = A[, C.idx]$; (m, k) dimensional array.
- R** `Array_like`.
row subset $R = A[R.idx,]$; (k, n) dimensional array.
- U** `array_like`;
connector matrix; (k, k) dimensional array.
- C.idx** `array_like`;
index set of the k selected columns used to form C .
- R.idx** `array_like`;
index set of the k selected rows used to form R .
- C.scores** `array_like`;
scores of the selected columns.
- R.scores** `array_like`;
scores of the selected rows.

```
## Not run:
# Load test image
data('tiger')

# Compute (column) randomized interpolative decomposition
# Note that the image needs to be transposed for correct plotting
out <- rcur(tiger, k = 150)

# Reconstruct image
tiger.re <- out$C %*% out$U %*% out$R
```

```

# Compute relative error
print(norm(tiger-tiger.re, 'F') / norm(tiger, 'F'))

# Plot approximated image
image(tiger.re, col = gray((0:255)/255))

## End(Not run)

```

rid

Randomized interpolative decomposition (ID).

Description

Randomized interpolative decomposition.

Usage

```

rid(A, k = NULL, mode = "column", p = 10, q = 0,
    idx_only = FALSE, rand = TRUE)

```

Arguments

A	array_like; numeric (m, n) input matrix (or data frame). If the data contain <i>NAs</i> na.omit is applied.
k	integer, optional; number of rows/columns to be selected. It is required that k is smaller or equal to $\min(m, n)$.
mode	string c('column', 'row'), optional; columns or rows ID.
p	integer, optional; oversampling parameter (default $p = 10$).
q	integer, optional. number of additional power iterations (default $q = 0$).
idx_only	bool, optional; if (<i>TRUE</i>), the index set <code>idx</code> is returned, but not the matrix <code>C</code> or <code>R</code> . This is more memory efficient, when dealing with large-scale data.
rand	bool, optional; if (<i>TRUE</i>), a probabilistic strategy is used, otherwise a deterministic algorithm is used.

Details

Algorithm for computing the ID of a rectangular (m, n) matrix A , with target rank $k \ll \min(m, n)$. The input matrix is factored as

$$A = C * Z$$

using the column pivoted QR decomposition. The factor matrix C is formed as a subset of columns of A , also called the partial column skeleton. If `mode='row'`, then the input matrix is factored as

$$A = Z * R$$

using the row pivoted QR decomposition. The factor matrix R is now formed as a subset of rows of A , also called the partial row skeleton. The factor matrix Z contains a (k, k) identity matrix as a submatrix, and is well-conditioned.

If `rand = 'TRUE'` a probabilistic strategy is used to compute the decomposition, otherwise a deterministic algorithm is used.

Value

`rid` returns a list containing the following components:

- C** array_like;
column subset $C = A[, idx]$, if `mode='column'`; array with dimensions (m, k) .
- R** array_like;
row subset $R = A[idx,]$, if `mode='row'`; array with dimensions (k, n) .
- Z** array_like;
well conditioned matrix; Depending on the selected mode, this is an array with dimensions (k, n) or (m, k) .
- idx** array_like;
index set of the k selected columns or rows used to form C or R .
- pivot** array_like;
information on the pivoting strategy used during the decomposition.
- scores** array_like;
scores of the columns or rows of the input matrix A .
- scores.idx** array_like;
scores of the k selected columns or rows in C or R .

rpca

Randomized principal component analysis (rpca).

Description

Fast computation of the principal components analysis using the randomized singular value decomposition.

Usage

```
rpca(A, k = NULL, center = TRUE, scale = TRUE, retx = TRUE,
      p = 10, q = 2, rand = TRUE)
```

Arguments

A array_like;
a numeric (m, n) input matrix (or data frame) to be analyzed.
If the data contain *NAs* na.omit is applied.

<code>k</code>	integer; number of dominant principle components to be computed. It is required that k is smaller or equal to $\min(m, n)$, but it is recommended that $k \ll \min(m, n)$.
<code>center</code>	bool, optional; logical value which indicates whether the variables should be shifted to be zero centered (<i>TRUE</i> by default).
<code>scale</code>	bool, optional; logical value which indicates whether the variables should be scaled to have unit variance (<i>TRUE</i> by default).
<code>retx</code>	bool, optional; logical value indicating whether the rotated variables / scores should be returned (<i>TRUE</i> by default).
<code>p</code>	integer, optional; oversampling parameter for <i>rsvd</i> (default $p = 10$), see <i>rsvd</i> .
<code>q</code>	integer, optional; number of additional power iterations for <i>rsvd</i> (default $q = 1$), see <i>rsvd</i> .
<code>rand</code>	bool, optional; if (<i>TRUE</i>), the <i>rsvd</i> routine is used, otherwise <i>svd</i> is used.

Details

Principal component analysis is an important linear dimension reduction technique.

Randomized PCA is computed via the randomized SVD algorithm (*rsvd*). The computational gain is substantial, if the desired number of principal components is relatively small, i.e. $k \ll \min(m, n)$.

The print and summary method can be used to present the results in a nice format. A scree plot can be produced with *ggscreeplot*. The individuals factor map can be produced with *ggindplot*, and a correlation plot with *ggcorplot*.

The predict function can be used to compute the scores of new observations. The data will automatically be centered (and scaled if requested). This is not fully supported for complex input matrices.

Value

rpca returns a list with class *rpca* containing the following components:

- rotation** array_like;
the rotation (eigenvectors); (n, k) dimensional array.
- eigvals** array_like;
eigenvalues; k dimensional vector.
- sdev** array_like;
standard deviations of the principal components; k dimensional vector.
- x** array_like;
the scores / rotated data; (m, k) dimensional array.
- center, scale** array_like;
the centering and scaling used.

Note

The principal components are not unique and only defined up to sign (a constant of modulus one in the complex case) and so may differ between different PCA implementations.

Similar to `prcomp` the variances are computed with the usual divisor $N - 1$.

rqb *Randomized QB Decomposition (rqb).*

Description

Compute the near-optimal QB decomposition of a rectangular matrix.

Usage

```
rqb(A, k = NULL, p = 10, q = 2, sdist = "normal", rand = TRUE)
```

Arguments

A	array_like; real/complex (m, n) input matrix (or data frame).
k	integer, optional; target rank of the low-rank decomposition. It should satisfy $k \ll \min(m, n)$.
p	integer, optional; oversampling parameter (default $p = 10$).
q	integer, optional; number of power iterations (default $q = 2$).
sdist	string $c('unif', 'normal', 'rademacher')$, optional; specifies the sampling distribution: 'unif': Uniform $[-1, 1]$. 'normal' (default): Normal $\sim N(0, 1)$. 'rademacher': Rademacher random variates.
rand	bool, optional; If (<i>TRUE</i>), a probabilistic strategy is used, otherwise a deterministic algorithm is used.

Details

The randomized QB decomposition factors a rectangular (m, n) matrix A as $A = Q * B$. Q is an (m, k) matrix with orthogonal columns, and B a (k, n) matrix. The target rank is assumed to be $k \ll \min(m, n)$.

p is an oversampling parameter to improve the approximation. A value between 5 and 10 is recommended, and $p = 10$ is set by default.

The parameter q specifies the number of power (subspace) iterations to reduce the approximation error. This is recommended if the the singular values decay slowly. In practice 1 or 2 iterations achieve good results, however, computing power iterations increases the computational time. The number of power iterations is set to $q = 2$ by default.

Value

`rrpca` returns a list containing the following components:

- Q** array_like;
matrix with orthogonal columns; (m, k) dimensional array.
- B** array_like;
smaller matrix; (k, n) dimensional array.

See Also

`svd`

`rrpca`

Randomized robust principal component analysis (rrpca).

Description

Robust principal components analysis separates a matrix into a low-rank plus sparse component.

Usage

```
rrpca(A, lambda = NULL, maxiter = 50, tol = 1e-05, p = 10, q = 2,
      trace = FALSE, rand = TRUE)
```

Arguments

- `A` array_like;
a real (m, n) input matrix (or data frame) to be decomposed.
na.omit is applied, if the data contain *NAs*.
- `lambda` scalar, optional;
tuning parameter (default $lambda = \max(m, n)^{-0.5}$).
- `maxiter` integer, optional;
maximum number of iterations (default $maxiter = 50$).

<code>tol</code>	scalar, optional; precision parameter (default $tol = 1.0e - 5$).
<code>p</code>	integer, optional; oversampling parameter for <i>rsvd</i> (default $p = 10$), see <i>rsvd</i> .
<code>q</code>	integer, optional; number of additional power iterations for <i>rsvd</i> (default $q = 2$), see <i>rsvd</i> .
<code>trace</code>	bool, optional; print progress.
<code>rand</code>	bool, optional; if (<i>TRUE</i>), the <i>rsvd</i> routine is used, otherwise <i>svd</i> is used.

Details

Robust principal component analysis (RPCA) is a method for the robust separation of a rectangular (m, n) matrix A into a low-rank component L and a sparse component S :

$$A = L + S$$

To decompose the matrix, we use the inexact augmented Lagrange multiplier method (IALM). The algorithm can be used in combination with either the randomized or deterministic SVD.

Value

`rrpca` returns a list containing the following components:

- L** array_like;
low-rank component; (m, n) dimensional array.
- S** array_like
sparse component; (m, n) dimensional array.

Examples

```

library('rsvd')

# Create toy video
# background frame
xy <- seq(-50, 50, length.out=100)
mgrid <- list( x=outer(xy*0,xy,FUN="+"), y=outer(xy,xy*0,FUN="+") )
bg <- 0.1*exp(sin(-mgrid$x**2-mgrid$y**2))
toyVideo <- matrix(rep(c(bg), 100), 100*100, 100)

# add moving object
for(i in 1:90) {
  mobject <- matrix(0, 100, 100)
  mobject[i:(10+i), 45:55] <- 0.2
  toyVideo[,i] = toyVideo[,i] + c( mobject )
}

# Foreground/Background separation
out <- rrpca(toyVideo, trace=TRUE)

# Display results of the seperation for the 10th frame
par(mfrow=c(1,4))
image(matrix(bg, ncol=100, nrow=100)) #true background
image(matrix(toyVideo[,10], ncol=100, nrow=100)) # frame
image(matrix(out$L[,10], ncol=100, nrow=100)) # seperated background
image(matrix(out$S[,10], ncol=100, nrow=100)) #seperated foreground

```

rsvd

Randomized Singular Value Decomposition (rsvd).

Description

The randomized SVD computes the near-optimal low-rank approximation of a rectangular matrix using a fast probabilistic algorithm.

Usage

```

rsvd(A, k = NULL, nu = NULL, nv = NULL, p = 10, q = 2,
      sdist = "normal")

```

Arguments

A	array_like; a real/complex (m, n) input matrix (or data frame) to be decomposed.
k	integer; specifies the target rank of the low-rank decomposition. k should satisfy $k \ll \min(m, n)$.

<code>nu</code>	integer, optional; number of left singular vectors to be returned. <i>nu</i> must be between 0 and <i>k</i> .
<code>nv</code>	integer, optional; number of right singular vectors to be returned. <i>nv</i> must be between 0 and <i>k</i> .
<code>p</code>	integer, optional; oversampling parameter (by default $p = 10$).
<code>q</code>	integer, optional; number of additional power iterations (by default $q = 2$).
<code>sdist</code>	string $c('uni f', 'normal', 'rademacher')$, optional; specifies the sampling distribution of the random test matrix: <i>'uni f'</i> : Uniform $[-1,1]$. <i>'normal'</i> (default) : Normal $\sim N(0,1)$. <i>'rademacher'</i> : Rademacher random variates.

Details

The singular value decomposition (SVD) plays an important role in data analysis, and scientific computing. Given a rectangular (m, n) matrix A , and a target rank $k \ll \min(m, n)$, the SVD factors the input matrix A as

$$A = U_k \text{diag}(d_k) V_k^\top$$

The k left singular vectors are the columns of the real or complex unitary matrix U . The k right singular vectors are the columns of the real or complex unitary matrix V . The k dominant singular values are the entries of d , and non-negative and real numbers.

p is an oversampling parameter to improve the approximation. A value of at least 10 is recommended, and $p = 10$ is set by default.

The parameter q specifies the number of power (subspace) iterations to reduce the approximation error. The power scheme is recommended, if the singular values decay slowly. In practice, 2 or 3 iterations achieve good results, however, computing power iterations increases the computational costs. The power scheme is set to $q = 2$ by default.

If $k > (\min(n, m)/4)$, a deterministic partial or truncated svd algorithm might be faster.

Value

`rsvd` returns a list containing the following three components:

- d** array_like;
singular values; vector of length (k) .
- u** array_like;
left singular vectors; (m, k) or (m, nu) dimensional array.
- v** array_like;
right singular vectors; (n, k) or (n, nv) dimensional array.

Note

The singular vectors are not unique and only defined up to sign (a constant of modulus one in the complex case). If a left singular vector has its sign changed, changing the sign of the corresponding right vector gives an equivalent decomposition.

Examples

```
library('rsvd')

# Create a n x n Hilbert matrix of order n,
# with entries H[i,j] = 1 / (i + j + 1).
hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "+") }
H <- hilbert(n=50)

# Low-rank (k=10) matrix approximation using rsvd
k=10
s <- rsvd(H, k=k)
Hre <- s$u %*% diag(s$d) %*% t(s$v) # matrix approximation
print(100 * norm(H - Hre, 'F') / norm(H, 'F')) # percentage error
# Compare to truncated base svd
s <- svd(H)
Hre <- s$u[,1:k] %*% diag(s$d[1:k]) %*% t(s$v[,1:k]) # matrix approximation
print(100 * norm(H - Hre, 'F') / norm(H, 'F')) # percentage error
```

tiger

Tiger

Description

1600x1200 grayscaled (8 bit [0-255]/255) image.

Usage

```
data('tiger')
```

Format

An object of class `rsvd`.

Examples

```
## Not run:  
library('rsvd')  
data('tiger')  
  
#Display image  
image(tiger, col = gray((0:255)/255))  
  
## End(Not run)
```
