Abstract

This is a collection of small examples to demonstrate Isabelle/HOL's (co)inductive definitions package. Large examples appear on many other sessions, such as Lambda, IMP, and Auth.

1 Common patterns of induction

theory *Common-Patterns*
imports *Main*
begin

The subsequent Isar proof schemes illustrate common proof patterns supported by the generic *induct* method.

To demonstrate variations on statement (goal) structure we refer to the induction rule of Peano natural numbers: $[\![P\ 0;\ \bigwedge nat.\ P\ nat \Longrightarrow P\ (Suc\ nat)]\!] \Longrightarrow P\ nat$, which is the simplest case of datatype induction. We shall also see more complex (mutual) datatype inductions involving several rules. Working with inductive predicates is similar, but involves explicit facts about membership, instead of implicit syntactic typing.

1.1 Variations on statement structure

1.1.1 Local facts and parameters

Augmenting a problem by additional facts and locally fixed variables is a bread-and-butter method in many applications. This is where unwieldy object-level $\forall$ and $\longrightarrow$ used to occur in the past. The *induct* method works with primary means of the proof language instead.

lemma
  fixes $n :: nat$
    and $x :: 'a$
  assumes $A\ n\ x$
  shows $P\ n\ x$ **using** ‹$A\ n\ x$›
proof (*induct n arbitrary*: x)
  case *0*
  note $prem = ‹A\ 0\ x›$
  show $P\ 0\ x$ **sorry**
next
  case (*Suc n*)
  note $hyp = ‹\bigwedge x.\ A\ n\ x \Longrightarrow P\ n\ x›$
    and $prem = ‹A\ (Suc\ n)\ x›$
  show $P\ (Suc\ n)\ x$ **sorry**
qed

1.1.2 Local definitions

Here the idea is to turn sub-expressions of the problem into a defined induction variable. This is often accompanied with fixing of auxiliary parameters in the original expression, otherwise the induction step would refer invariably to particular entities. This combination essentially expresses a partially abstracted representation of inductive expressions.

lemma

```
  fixes a :: 'a ⇒ nat
  assumes A (a x)
  shows P (a x) using ‹A (a x)›
proof (induct n ≡ a x arbitrary: x)
  case 0
  note prem = ‹A (a x)›
    and defn = ‹0 = a x›
  show P (a x) sorry
next
  case (Suc n)
  note hyp = ‹⋀x. n = a x ⟹ A (a x) ⟹ P (a x)›
    and prem = ‹A (a x)›
    and defn = ‹Suc n = a x›
  show P (a x) sorry
qed
```

Observe how the local definition $n = a\ x$ recurs in the inductive cases as $0 = a\ x$ and $Suc\ n = a\ x$, according to underlying induction rule.

1.1.3 Simple simultaneous goals

The most basic simultaneous induction operates on several goals one-by-one, where each case refers to induction hypotheses that are duplicated according to the number of conclusions.

```
lemma
  fixes n :: nat
  shows P n and Q n
proof (induct n)
  case 0 case 1
  show P 0 sorry
next
  case 0 case 2
  show Q 0 sorry
next
  case (Suc n) case 1
  note hyps = ‹P n› ‹Q n›
  show P (Suc n) sorry
next
  case (Suc n) case 2
  note hyps = ‹P n› ‹Q n›
  show Q (Suc n) sorry
qed
```

The split into subcases may be deferred as follows – this is particularly relevant for goal statements with local premises.

```
lemma
  fixes n :: nat
  shows A n ⟹ P n
```

```
    and B n ⟹ Q n
proof (induct n)
  case 0
  {
    case 1
    note ‹A 0›
    show P 0 sorry
  next
    case 2
    note ‹B 0›
    show Q 0 sorry
  }
next
  case (Suc n)
  note ‹A n ⟹ P n›
    and ‹B n ⟹ Q n›
  {
    case 1
    note ‹A (Suc n)›
    show P (Suc n) sorry
  next
    case 2
    note ‹B (Suc n)›
    show Q (Suc n) sorry
  }
qed
```

1.1.4 Compound simultaneous goals

The following pattern illustrates the slightly more complex situation of simultaneous goals with individual local assumptions. In compound simultaneous statements like this, local assumptions need to be included into each goal, using $\Longrightarrow$ of the Pure framework. In contrast, local parameters do not require separate $\bigwedge$ prefixes here, but may be moved into the common context of the whole statement.

```
lemma
  fixes n :: nat
    and x :: 'a
    and y :: 'b
  shows A n x ⟹ P n x
    and B n y ⟹ Q n y
proof (induct n arbitrary: x y)
  case 0
  {
    case 1
    note prem = ‹A 0 x›
    show P 0 x sorry
  }
```

```
  {
    case 2
    note prem = ‹B 0 y›
    show Q 0 y sorry
  }
next
  case (Suc n)
  note hyps = ‹⋀x. A n x ⟹ P n x› ‹⋀y. B n y ⟹ Q n y›
  then have some-intermediate-result sorry
  {
    case 1
    note prem = ‹A (Suc n) x›
    show P (Suc n) x sorry
  }
  {
    case 2
    note prem = ‹B (Suc n) y›
    show Q (Suc n) y sorry
  }
qed
```

Here *induct* provides again nested cases with numbered sub-cases, which allows to share common parts of the body context. In typical applications, there could be a long intermediate proof of general consequences of the induction hypotheses, before finishing each conclusion separately.

1.2 Multiple rules

Multiple induction rules emerge from mutual definitions of datatypes, inductive predicates, functions etc. The *induct* method accepts replicated arguments (with *and* separator), corresponding to each projection of the induction principle.

The goal statement essentially follows the same arrangement, although it might be subdivided into simultaneous sub-problems as before!

```
datatype foo = Foo1 nat | Foo2 bar
  and bar = Bar1 bool | Bar2 bazar
  and bazar = Bazar foo
```

The pack of induction rules for this datatype is:

```
⟦⋀nat. P1 (Foo1 nat); ⋀bar. P2 bar ⟹ P1 (Foo2 bar); ⋀bool. P2 (Bar1 bool);
 ⋀bazar. P3 bazar ⟹ P2 (Bar2 bazar); ⋀foo. P1 foo ⟹ P3 (Bazar foo)⟧
⟹ P1 foo
⟦⋀nat. P1 (Foo1 nat); ⋀bar. P2 bar ⟹ P1 (Foo2 bar); ⋀bool. P2 (Bar1 bool);
 ⋀bazar. P3 bazar ⟹ P2 (Bar2 bazar); ⋀foo. P1 foo ⟹ P3 (Bazar foo)⟧
⟹ P2 bar
⟦⋀nat. P1 (Foo1 nat); ⋀bar. P2 bar ⟹ P1 (Foo2 bar); ⋀bool. P2 (Bar1 bool);
 ⋀bazar. P3 bazar ⟹ P2 (Bar2 bazar); ⋀foo. P1 foo ⟹ P3 (Bazar foo)⟧
```

$\Longrightarrow$ *P3 bazar*

This corresponds to the following basic proof pattern:

```
lemma
  fixes foo :: foo
    and bar :: bar
    and bazar :: bazar
  shows P foo
    and Q bar
    and R bazar
proof (induct foo and bar and bazar)
  case (Foo1 n)
  show P (Foo1 n) sorry
next
  case (Foo2 bar)
  note ‹Q bar›
  show P (Foo2 bar) sorry
next
  case (Bar1 b)
  show Q (Bar1 b) sorry
next
  case (Bar2 bazar)
  note ‹R bazar›
  show Q (Bar2 bazar) sorry
next
  case (Bazar foo)
  note ‹P foo›
  show R (Bazar foo) sorry
qed
```

This can be combined with the previous techniques for compound statements, e.g. like this.

```
lemma
  fixes x :: 'a and y :: 'b and z :: 'c
    and foo :: foo
    and bar :: bar
    and bazar :: bazar
  shows
    A x foo ⟹ P x foo
  and
    B1 y bar ⟹ Q1 y bar
    B2 y bar ⟹ Q2 y bar
  and
    C1 z bazar ⟹ R1 z bazar
    C2 z bazar ⟹ R2 z bazar
    C3 z bazar ⟹ R3 z bazar
proof (induct foo and bar and bazar arbitrary: x and y and z)
  oops
```

1.3 Inductive predicates

The most basic form of induction involving predicates (or sets) essentially eliminates a given membership fact.

```
inductive Even :: nat ⇒ bool where
  zero: Even 0
| double: Even n ⟹ Even (2 * n)

lemma
  assumes Even n
  shows P n
  using assms
proof induct
  case zero
  show P 0 sorry
next
  case (double n)
  note ‹Even n› and ‹P n›
  show P (2 * n) sorry
qed
```

Alternatively, an initial rule statement may be proven as follows, performing "in-situ" elimination with explicit rule specification.

```
lemma Even n ⟹ P n
proof (induct rule: Even.induct)
  oops
```

Simultaneous goals do not introduce anything new.

```
lemma
  assumes Even n
  shows P1 n and P2 n
  using assms
proof induct
  case zero
  {
    case 1
    show P1 0 sorry
  next
    case 2
    show P2 0 sorry
  }
next
  case (double n)
  note ‹Even n› and ‹P1 n› and ‹P2 n›
  {
    case 1
    show P1 (2 * n) sorry
  next
```

```
    case 2
    show P2 (2 * n) sorry
  }
qed
```

Working with mutual rules requires special care in composing the statement as a two-level conjunction, using lists of propositions separated by *and*. For example:

```
inductive Evn :: nat ⇒ bool and Odd :: nat ⇒ bool
where
  zero: Evn 0
| succ-Evn: Evn n ⟹ Odd (Suc n)
| succ-Odd: Odd n ⟹ Evn (Suc n)

lemma
    Evn n ⟹ P1 n
    Evn n ⟹ P2 n
    Evn n ⟹ P3 n
  and
    Odd n ⟹ Q1 n
    Odd n ⟹ Q2 n
proof (induct rule: Evn-Odd.inducts)
  case zero
  { case 1 show P1 0 sorry }
  { case 2 show P2 0 sorry }
  { case 3 show P3 0 sorry }
next
  case (succ-Evn n)
  note ‹Evn n› and ‹P1 n› ‹P2 n› ‹P3 n›
  { case 1 show Q1 (Suc n) sorry }
  { case 2 show Q2 (Suc n) sorry }
next
  case (succ-Odd n)
  note ‹Odd n› and ‹Q1 n› ‹Q2 n›
  { case 1 show P1 (Suc n) sorry }
  { case 2 show P2 (Suc n) sorry }
  { case 3 show P3 (Suc n) sorry }
qed

end
```

2 Defining an Initial Algebra by Quotienting a Free Algebra

2.1 Defining the Free Algebra

Messages with encryption and decryption as free constructors.

datatype
freemsg = *NONCE nat*
| *MPAIR freemsg freemsg*
| *CRYPT nat freemsg*
| *DECRYPT nat freemsg*

The equivalence relation, which makes encryption and decryption inverses provided the keys are the same.

The first two rules are the desired equations. The next four rules make the equations applicable to subterms. The last two rules are symmetry and transitivity.

inductive-set
msgrel :: (*freemsg* ∗ *freemsg*) *set*
and *msg-rel* :: [*freemsg*, *freemsg*] => *bool* (**infixl** ∼ *50*)
where
X ∼ *Y* == (*X*,*Y*) ∈ *msgrel*
| *CD*: *CRYPT K* (*DECRYPT K X*) ∼ *X*
| *DC*: *DECRYPT K* (*CRYPT K X*) ∼ *X*
| *NONCE*: *NONCE N* ∼ *NONCE N*
| *MPAIR*: ⟦*X* ∼ *X'*; *Y* ∼ *Y'*⟧ ⟹ *MPAIR X Y* ∼ *MPAIR X' Y'*
| *CRYPT*: *X* ∼ *X'* ⟹ *CRYPT K X* ∼ *CRYPT K X'*
| *DECRYPT*: *X* ∼ *X'* ⟹ *DECRYPT K X* ∼ *DECRYPT K X'*
| *SYM*: *X* ∼ *Y* ⟹ *Y* ∼ *X*
| *TRANS*: ⟦*X* ∼ *Y*; *Y* ∼ *Z*⟧ ⟹ *X* ∼ *Z*

2.2 Some Functions on the Free Algebra

2.2.1 The Set of Nonces

A function to return the set of nonces present in a message. It will be lifted to the initial algrebra, to serve as an example of that process.

consts

freenonces :: *freemsg* ⇒ *nat set*

primrec
freenonces (*NONCE N*) = {*N*}
freenonces (*MPAIR X Y*) = *freenonces X* ∪ *freenonces Y*
freenonces (*CRYPT K X*) = *freenonces X*
freenonces (*DECRYPT K X*) = *freenonces X*

This theorem lets us prove that the nonces function respects the equivalence relation. It also helps us prove that Nonce (the abstract constructor) is injective

theorem *msgrel-imp-eq-freenonces*: *U* ∼ *V* ⟹ *freenonces U* = *freenonces V*
by (*induct set*: *msgrel*) *auto*

2.2.2 The Left Projection

A function to return the left part of the top pair in a message. It will be lifted to the initial algrebra, to serve as an example of that process.

consts *freeleft* :: *freemsg* ⇒ *freemsg*
primrec
freeleft (*NONCE N*) = *NONCE N*
freeleft (*MPAIR X Y*) = *X*
freeleft (*CRYPT K X*) = *freeleft X*
freeleft (*DECRYPT K X*) = *freeleft X*

This theorem lets us prove that the left function respects the equivalence relation. It also helps us prove that MPair (the abstract constructor) is injective

theorem *msgrel-imp-eqv-freeleft*:
U ∼ *V* ⟹ *freeleft U* ∼ *freeleft V*
by (*induct set*: *msgrel*) (*auto intro*: *msgrel.intros*)

2.2.3 The Right Projection

A function to return the right part of the top pair in a message.

consts *freeright* :: *freemsg* ⇒ *freemsg*
primrec
freeright (*NONCE N*) = *NONCE N*
freeright (*MPAIR X Y*) = *Y*
freeright (*CRYPT K X*) = *freeright X*
freeright (*DECRYPT K X*) = *freeright X*

This theorem lets us prove that the right function respects the equivalence relation. It also helps us prove that MPair (the abstract constructor) is injective

theorem *msgrel-imp-eqv-freeright*:

$U \sim V \Longrightarrow \mathit{freeright}\ U \sim \mathit{freeright}\ V$
by (*induct set*: *msgrel*) (*auto intro*: *msgrel.intros*)

2.2.4 The Discriminator for Constructors

A function to distinguish nonces, mpairs and encryptions

consts *freediscrim* :: *freemsg* ⇒ *int*
primrec
$\mathit{freediscrim}\ (\mathit{NONCE}\ N) = 0$
$\mathit{freediscrim}\ (\mathit{MPAIR}\ X\ Y) = 1$
$\mathit{freediscrim}\ (\mathit{CRYPT}\ K\ X) = \mathit{freediscrim}\ X + 2$
$\mathit{freediscrim}\ (\mathit{DECRYPT}\ K\ X) = \mathit{freediscrim}\ X - 2$

This theorem helps us prove $\mathit{Nonce}\ N \neq \mathit{MPair}\ X\ Y$

theorem *msgrel-imp-eq-freediscrim*:
$U \sim V \Longrightarrow \mathit{freediscrim}\ U = \mathit{freediscrim}\ V$
by (*induct set*: *msgrel*) *auto*

3.2 Some Functions on the Free Algebra

3.2.1 The Set of Variables

A function to return the set of variables present in a message. It will be lifted to the initial algrebra, to serve as an example of that process. Note that the "free" refers to the free datatype rather than to the concept of a free variable.

Lemma for *Function-eval*. The major premise is that (*c*,*s*) executes to *s1* using eval restricted to its functional part. Note that the execution (*c*,*s*) −[*eval*]−> *s2* can use unrestricted *eval*! The reason is that the execution (*c*,*s*) −[*eval Int* {...}]−> *s1* assures us that execution is functional on the argument (*c*,*s*).
