Chapter 1

Overview

These theories, called Bali, model and analyse different aspects of the JavaCard **source language**. The basis is an abstract model of the JavaCard source language. On it, a type system, an operational semantics and an axiomatic semantics (Hoare logic) are built. The execution of a wellformed program (with respect to the type system) according to the operational semantics is proved to be typesafe. The axiomatic semantics is proved to be sound and relative complete with respect to the operational semantics.
We have modelled large parts of the original JavaCard source language. It models features such as:

- The basic "primitive types" of Java
- Classes and related concepts
- Class fields and methods
- Instance fields and methods
- Interfaces and related concepts
- Arrays
- Static initialisation
- Static overloading of fields and methods
- Inheritance, overriding and hiding of methods, dynamic binding
- All cases of abrupt termination
  - Exception throwing and handling
  - `break`, `continue` and `return`
- Packages
- Access Modifiers (`private`, `protected`, `public`)
- A "definite assignment" check

The following features are missing in Bali wrt. JavaCard:

- Some primitive types (`byte, short`)
- Syntactic variants of statements (`do`-loop, `for`-loop)
- Interface fields

- Inner Classes

In addition, features are missing that are not part of the JavaCard language, such as multithreading and garbage collection. No attempt has been made to model peculiarities of JavaCard such as the applet firewall or the transaction mechanism.
Overview of the theories:

Basis Some basic definitions and settings not specific to JavaCard but missing in HOL.

Table Definition and some properties of a lookup table to map various names (like class names or method names) to some content (like classes or methods).

Name Definition of various names (class names, variable names, package names,...)

Value JavaCard expression values (Boolean, Integer, Addresses,...)

Type JavaCard types. Primitive types (Boolean, Integer,...) and reference types (Classes, Interfaces, Arrays,...)

Term JavaCard terms. Variables, expressions and statements.

Decl Class, interface and program declarations. Recursion operators for the class and the interface hierarchy.

TypeRel Various relations on types like the subclass-, subinterface-, widening-, narrowing- and casting-relation.

DeclConcepts Advanced concepts on the class and interface hierarchy like inheritance, overriding, hiding, accessibility of types and members according to the access modifiers, method lookup.

WellType Typesystem on the JavaCard term level.

DefiniteAssignment The definite assignment analysis on the JavaCard term level.

WellForm Typesystem on the JavaCard class, interface and program level.

State The program state (like object store) for the execution of JavaCard. Abrupt completion (exceptions, break, continue, return) is modelled as flag inside the state.

Eval Operational (big step) semantics for JavaCard.

Example An concrete example of a JavaCard program to validate the typesystem and the operational semantics.

Conform Conformance predicate for states. When does an execution state conform to the static types of the program given by the typesystem.

DefiniteAssignmentCorrect Correctness of the definite assignment analysis. If the analysis regards a variable as definitely assigned at a certain program point, the variable will actually be assigned there during execution.

TypeSafe Typesafety proof of the execution of JavaCard. "Welltyped programs don't go wrong" or more technical: The execution of a welltyped JavaCard program preserves the conformance of execution states.

Evaln Copy of the operational semantics given in theory Eval expanded with an annotation for the maximal recursive depth. The semantics is not altered. The annotation is needed for the soundness proof of the axiomatic semantics.

Trans A smallstep operational semantics for JavaCard.

AxSem An axiomatic semantics (Hoare logic) for JavaCard.

AxSound The soundness proof of the axiomatic semantics with respect to the operational semantics.

AxCompl The proof of (relative) completeness of the axiomatic semantics with respect to the operational semantics.

AxExample An concrete example of the axiomatic semantics at work, applied to prove some properties of the JavaCard example given in theory Example.

Chapter 3

Table

2 Abstract tables and their implementation as lists

theory *Table* **imports** *Basis* **begin**

design issues:

- definition of table: infinite map vs. list vs. finite set list chosen, because:
  - \+ a priori finite
  - \+ lookup is more operational than for finite set
  - \- not very abstract, but function table converts it to abstract mapping
- coding of lookup result: Some/None vs. value/arbitrary Some/None chosen, because:
  - ++ makes definedness check possible (applies also to finite set), which is important for the type standard, hiding/overriding, etc. (though it may perhaps be possible at least for the operational semantics to treat programs as infinite, i.e. where classes, fields, methods etc. of any name are considered to be defined)
  - \- sometimes awkward case distinctions, alleviated by operator 'the'

types $('a, 'b)$ *table* — table with key type 'a and contents type 'b
$= 'a \rightharpoonup 'b$
$('a, 'b)$ *tables* — non-unique table with key 'a and contents 'b
$= 'a \Rightarrow 'b$ *set*

map of / table of

abbreviation
table-of :: $('a \times 'b)$ *list* $\Rightarrow$ $('a, 'b)$ *table* — concrete table

⟨*proof*⟩

end

Chapter 7

Term

6 Java expressions and statements

theory *Term* **imports** *Value Table* **begin**

design issues:

- invocation frames for local variables could be reduced to special static objects (one per method). This would reduce redundancy, but yield a rather non-standard execution model more difficult to understand.
- method bodies separated from calls to handle assumptions in axiomat. semantics NB: Body is intended to be in the environment of the called method.
- class initialization is regarded as (auxiliary) statement (required for AxSem)
- result expression of method return is handled by a special result variable result variable is treated uniformly with local variables
  - \+ welltypedness and existence of the result/return expression is ensured without extra efford

simplifications:

- expression statement allowed for any expression
- This is modeled as a special non-assignable local variable
- Super is modeled as a general expression with the same value as This
- access to field x in current class via This.x
- NewA creates only one-dimensional arrays; initialization of further subarrays may be simulated with nested NewAs
- The 'Lit' constructor is allowed to contain a reference value. But this is assumed to be prohibited in the input language, which is enforced by the type-checking rules.
- a call of a static method via a type name may be simulated by a dummy variable
- no nested blocks with inner local variables
- no synchronized statements
- no secondary forms of if, while (e.g. no for) (may be easily simulated)
- no switch (may be simulated with if)
- the *try-catch-finally* statement is divided into the *try-catch* statement and a finally statement, which may be considered as try..finally with empty catch
- the *try-catch* statement has exactly one catch clause; multiple ones can be simulated with instanceof
- the compiler is supposed to add the annotations - during type-checking. This transformation is left out as its result is checked by the type rules anyway

types *locals* = (*lname*, *val*) *table* — local variables

datatype *jump*
= *Break label* — break

| *Cont label* — continue
| *Ret* — return from method

datatype *xcpt* — exception
= *Loc loc* — location of allocated execption object
| *Std xname* — intermediate standard exception, see Eval.thy

datatype *error*
= *AccessViolation* — Access to a member that isn't permitted
| *CrossMethodJump* — Method exits with a break or continue

datatype *abrupt* — abrupt completion
= *Xcpt xcpt* — exception
| *Jump jump* — break, continue, return
| *Error error* — runtime errors, we wan't to detect and proof absent in welltyped programms
types
abopt = *abrupt option*

Local variable store and exception. Anticipation of State.thy used by smallstep semantics. For a method call, we save the local variables of the caller in the term Callee to restore them after method return. Also an exception must be restored after the finally statement

translations
(*type*) *locals* <= (*type*) (*lname*, *val*) *table*

datatype *inv-mode* — invocation mode for method calls
= *Static* — static
| *SuperM* — super
| *IntVir* — interface or virtual

record *sig* = — signature of a method, cf. 8.4.2
name ::*mname* — acutally belongs to Decl.thy
parTs::*ty list*

translations
(*type*) *sig* <= (*type*) (|*name*::*mname*,*parTs*::*ty list*|)
(*type*) *sig* <= (*type*) (|*name*::*mname*,*parTs*::*ty list*,...::'*a*|)

— function codes for unary operations
datatype *unop* = *UPlus* — + unary plus
| *UMinus* — - unary minus
| *UBitNot* — bitwise NOT
| *UNot* — ! logical complement

— function codes for binary operations
datatype *binop* = *Mul* — * multiplication
| *Div* — / division
| *Mod* — % remainder
| *Plus* — + addition
| *Minus* — - subtraction
| *LShift* — << left shift
| *RShift* — >> signed right shift
| *RShiftU* — >>> unsigned right shift
| *Less* — < less than
| *Le* — <= less than or equal
| *Greater* — > greater than
| *Ge* — >= greater than or equal
| *Eq* — == equal
| *Neq* — != not equal

| *BitAnd* — `&` bitwise AND
| *And* — `&` boolean AND
| *BitXor* — `^` bitwise Xor
| *Xor* — `^` boolean Xor
| *BitOr* — `|` bitwise Or
| *Or* — `|` boolean Or
| *CondAnd* — `&&` conditional And
| *CondOr* — `||` conditional Or

The boolean operators `&` and `|` strictly evaluate both of their arguments. The conditional operators `&&` and `||` only evaluate the second argument if the value of the whole expression isn't allready determined by the first argument. e.g.: `false && e` e is not evaluated; `true || e` e is not evaluated;

datatype *var*

— *c2*: block to execute when exception is cateched
| *Fin stmt stmt* (- *Finally* - [79,79]70)
| *FinA abopt stmt* — Save abruption of first statement
— technical term for smallstep sem.)
| *Init qtname* — class initialization

The expressions Methd and Body are artificial program constructs, in the sense that they are not used to define a concrete Bali program. In the operational semantic's they are "generated on the fly" to decompose the task to define the behaviour of the Call expression. They are crucial for the axiomatic semantics to give a syntactic hook to insert some assertions (cf. AxSem.thy, Eval.thy). The Init statement (to initialize a class on its first use) is inserted in various places by the semantics. Callee, InsInitV, InsInitE,FinA are only needed as intermediate steps in the smallstep (transition) semantics (cf. Trans.thy). Callee is used to save the local variables of the caller for method return. So ve avoid modelling a frame stack. The InsInitV/E terms are only used by the smallstep semantics to model the intermediate steps of class-initialisation.

⟨*ML*⟩

declare *is-stmt-rews* [*simp*]

Here is some syntactic stuff to handle the injections of statements, expressions, variables and expression lists into general terms.

abbreviation (*input*)
expr-inj-term :: *expr* ⇒ *term* (⟨-⟩$_e$ *1000*)
where ⟨*e*⟩$_e$ == *In1l e*

abbreviation (*input*)
stmt-inj-term :: *stmt* ⇒ *term* (⟨-⟩$_s$ *1000*)
where ⟨*c*⟩$_s$ == *In1r c*

abbreviation (*input*)
var-inj-term :: *var* ⇒ *term* (⟨-⟩$_v$ *1000*)
where ⟨*v*⟩$_v$ == *In2 v*

abbreviation (*input*)
lst-inj-term :: *expr list* ⇒ *term* (⟨-⟩$_l$ *1000*)
where ⟨*es*⟩$_l$ == *In3 es*

It seems to be more elegant to have an overloaded injection like the following.

class *inj-term* =
fixes *inj-term*:: *'a* ⇒ *term* (⟨-⟩ *1000*)

How this overloaded injections work can be seen in the theory *DefiniteAssignment*. Other big inductive relations on terms defined in theories *WellType*, *Eval*, *Evaln* and *AxSem* don't follow this convention right now, but introduce subtle syntactic sugar in the relations themselves to make a distinction on expressions, statements and so on. So unfortunately you will encounter a mixture of dealing with these injections. The abbreviations above are used as bridge between the different conventions.

Chapter 8

Decl

7 Field, method, interface, and class declarations, whole Java programs

theory *Decl*
imports *Term Table*
begin

improvements:

- clarification and correction of some aspects of the package/access concept (Also submitted as bug report to the Java Bug Database: Bug Id: 4485402 and Bug Id: 4493343 http://developer.java.su)

simplifications:

- the only field and method modifiers are static and the access modifiers
- no constructors, which may be simulated by new + suitable methods
- there is just one global initializer per class, which can simulate all others
- no throws clause
- a void method is replaced by one that returns Unit (of dummy type Void)
- no interface fields
- every class has an explicit superclass (unused for Object)
- the (standard) methods of Object and of standard exceptions are not specified
- no main method

8 Modifier

Access modifier

datatype *acc-modi*
$= Private \mid Package \mid Protected \mid Public$

We can define a linear order for the access modifiers. With Private yielding the most restrictive access and public the most liberal access policy: Private ¡ Package ¡ Protected ¡ Public

instantiation *acc-modi* :: *linorder*
begin

definition
less-acc-def: $a < b$
$\longleftrightarrow$ (*case a of*
Private $\Rightarrow (b{=}Package \vee b{=}Protected \vee b{=}Public)$
$\mid$ *Package* $\Rightarrow (b{=}Protected \vee b{=}Public)$
$\mid$ *Protected* $\Rightarrow (b{=}Public)$
$\mid$ *Public* $\Rightarrow False$)

definition
le-acc-def: $(a :: acc\text{-}modi) \leq b \longleftrightarrow a < b \vee a = b$

instance ⟨*proof*⟩

end

lemma *acc-modi-top* [*simp*]: $Public \leq a \Longrightarrow a = Public$
⟨*proof*⟩

lemma *acc-modi-top1* [*simp*, *intro*!]: $a \leq Public$
⟨*proof*⟩

lemma *acc-modi-le-Public*:
$a \leq Public \Longrightarrow a{=}Private \vee a = Package \vee a{=}Protected \vee a{=}Public$
⟨*proof*⟩

lemma *acc-modi-bottom*: $a \leq Private \Longrightarrow a = Private$
⟨*proof*⟩

lemma *acc-modi-Private-le*:
$Private \leq a \Longrightarrow a{=}Private \vee a = Package \vee a{=}Protected \vee a{=}Public$
⟨*proof*⟩

Chapter 9

TypeRel

15 The relations between Java types

theory *TypeRel* **imports** *Decl* **begin**

simplifications:

- subinterface, subclass and widening relation includes identity

improvements over Java Specification 1.0:

- narrowing reference conversion also in cases where the return types of a pair of methods common to both types are in widening (rather identity) relation
- one could add similar constraints also for other cases

design issues:

- the type relations do not require *is-type* for their arguments
- the subint1 and subcls1 relations imply *is-iface*/*is-class* for their first arguments, which is required for their finiteness

consts

implmt1 :: *prog* ⇒ (*qtname* × *qtname*) *set* — direct implementation

18 accessibility of members

The accessibility of members is more involved as the accessibility of types. We have to distinguish several cases to model the different effects of accessibility during inheritance, overriding and ordinary member access

Various technical conversion and selection functions

members

inductive
members :: *prog* ⇒ (*qtname* × *memberdecl*) ⇒ *qtname* ⇒ *bool*
(- ⊢ - *member'-of* - [*61*,*61*,*61*] *60*)
for *G* :: *prog*
where

Immediate: ⟦*G*⊢*mbr m declared-in C*;*declclass m* = *C*⟧ ⟹ *G*⊢*m member-of C*
| *Inherited*: ⟦*G*⊢*m inheritable-in* (*pid C*); *G*⊢*memberid m undeclared-in C*;
G⊢*C* ≺$_C$ *1 S*; *G*⊢(*Class S*) *accessible-in* (*pid C*);*G*⊢*m member-of S*
⟧ ⟹ *G*⊢*m member-of C*

Note that in the case of an inherited member only the members of the direct superclass are concerned. If a member of a superclass of the direct superclass isn't inherited in the direct superclass (not member of the direct superclass) than it can't be a member of the class. E.g. If a member of a class A is defined with package access it isn't member of a subclass S if S isn't in the same package as A. Any further subclasses of S will not inherit the member, regardless if they are in the same package as A or not.

permits access

definition *permits-acc* :: *prog* $\Rightarrow$ (*qtname* $\times$ *memberdecl*) $\Rightarrow$ *qtname* $\Rightarrow$ *qtname* $\Rightarrow$ *bool* (- $\vdash$ - *in* - *permits'-acc'-from* - [*61*,*61*,*61*,*61*] *60*) **where**
$G\vdash$*membr in cls permits-acc-from accclass*
$\equiv$ (*case* (*accmodi membr*) *of*
Private $\Rightarrow$ (*declclass membr* = *accclass*)
| *Package* $\Rightarrow$ (*pid* (*declclass membr*) = *pid accclass*)
| *Protected* $\Rightarrow$ (*pid* (*declclass membr*) = *pid accclass*)
$\vee$
($G\vdash$*accclass* $\prec_C$ *declclass membr*
$\wedge$ ($G\vdash$*cls* $\preceq_C$ *accclass* $\vee$ *is-static membr*))

| *Public* ⇒ *True*)

The subcondition of the *Protected* case: $G\vdash accclass \prec_C declclass\ membr$ could also be relaxed to: $G\vdash accclass \preceq_C declclass\ membr$ since in case both classes are the same the other condition *pid* (*declclass membr*) = *pid accclass* holds anyway.

Like in case of overriding, the static and dynamic accessibility of members is not uniform.

- Statically the class/interface of the member must be accessible for the member to be accessible. During runtime this is not necessary. For Example, if a class is accessible and we are allowed to access a member of this class (statically) we expect that we can access this member in an arbitrary subclass (during runtime). It's not intended to restrict the access to accessible subclasses during runtime.
- Statically the member we want to access must be "member of" the class. Dynamically it must only be "member in" the class.

subcls-mthds
++
table-of (*map* (λ(*s*,*m*). (*s*,*C*,*m*)) (*methods c*)))

methd G C: methods of a class C (statically visible from C), with inheritance and hiding cf. 8.4.6; Overriding is captured by *dynmethd*. Every new method with the same signature coalesces the method of a superclass.

definition *accmethd* :: *prog* ⇒ *qtname* ⇒ *qtname* ⇒ (*sig*,*qtname* × *methd*) *table* **where**
accmethd G S C
≡ *filter-tab* (λ*sig m*. $G \vdash method\ sig\ m\ of\ C\ accessible\text{-}from\ S$)
(*methd G C*)

accmethd G S C: only those methods of *methd G C*, accessible from S

Note the class component in the accessibility filter. The class where method m is declared (*declC*) isn't necessarily accessible from the current scope S. The method can be made accessible through inheritance, too. So we must test accessibility of method m of class C (not *declclass m*)

```
definition dynmethd :: prog ⇒ qtname ⇒ qtname ⇒ (sig,qtname × methd) table where
dynmethd G statC dynC
 ≡ λ sig.
   (if G⊢dynC ≼C statC
    then (case methd G statC sig of
            None ⇒ None
          | Some statM
            ⇒ (class-rec G dynC empty
                 (λC c subcls-mthds.
                    subcls-mthds
                    ++
                    (filter-tab
                      (λ - dynM. G,sig⊢dynM overrides statM ∨ dynM=statM)
                      (methd G C) ))
               ) sig
         )
    else None)
```

dynmethd G statC dynC: dynamic method lookup of a reference with dynamic class *dynC* and static class *statC*

Note some kind of duality between *methd* and *dynmethd* in the *class-rec* arguments. Whereas *methd* filters the subclass methods (to get only the inherited ones), *dynmethd* filters the new methods (to get only those methods which actually override the methods of the static class)

```
definition dynimethd :: prog ⇒ qtname ⇒ qtname ⇒ (sig,qtname × methd) table where
dynimethd G I dynC
 ≡ λ sig. if imethds G I sig ≠ {}
          then methd G dynC sig
          else dynmethd G Object dynC sig
```

dynimethd G I dynC: dynamic method lookup of a reference with dynamic class dynC and static interface type I

When calling an interface method, we must distinguish if the method signature was defined in the interface or if it must be an Object method in the other case. If it was an interface method we search the class hierarchy starting at the dynamic class of the object up to Object to find the first matching method (*methd*). Since all interface methods have public access the method can't be coalesced due to some odd visibility effects like in case of dynmethd. The method will be inherited or overridden in all classes from the first class implementing the interface down to the actual dynamic class.

```
definition dynlookup :: prog ⇒ ref-ty ⇒ qtname ⇒ (sig,qtname × methd) table where
dynlookup G statT dynC
 ≡ (case statT of
      NullT       ⇒ empty
    | IfaceT I    ⇒ dynimethd G I      dynC
    | ClassT statC ⇒ dynmethd  G statC  dynC
    | ArrayT ty   ⇒ dynmethd  G Object dynC)
```

dynlookup G statT dynC: dynamic lookup of a method within the static reference type statT and the dynamic class dynC. In a wellformd context statT will not be NullT and in case statT is an array type, dynC=Object

```
definition fields :: prog ⇒ qtname ⇒ ((vname × qtname) × field) list where
fields G C
```

$\equiv$ *class-rec G C* [] ($\lambda C\ c\ ts.$ *map* ($\lambda(n,t).$ ((n,C),t)) (*cfields c*) @ *ts*)

field-tab

accfield G C S: fields of a class C which are accessible from scope of class S with inheritance and hiding, cf. 8.3

note the class component in the accessibility filter (see also *methd*). The class declaring field f (*declC*) isn't necessarily accessible from scope S. The field can be made visible through inheritance, too. So we must test accessibility of field f of class C (not *declclass f*)

Chapter 11

WellType

28 Well-typedness of Java programs

theory *WellType*
imports *DeclConcepts*
begin

improvements over Java Specification 1.0:

- methods of Object can be called upon references of interface or array type

simplifications:

- the type rules include all static checks on statements and expressions, e.g. definedness of names (of parameters, locals, fields, methods)

design issues:

- unified type judgment for statements, variables, expressions, expression lists
- statements are typed like expressions with dummy type Void
- the typing rules take an extra argument that is capable of determining the dynamic type of objects. Therefore, they can be used for both checking static types and determining runtime types in transition semantics.

types *lenv*

DefiniteAssignment

29 Definite Assignment

theory *DefiniteAssignment* **imports** *WellType* **begin**

Definite Assignment Analysis (cf. 16)

The definite assignment analysis approximates the sets of local variables that will be assigned at a certain point of evaluation, and ensures that we will only read variables which previously were assigned. It should conform to the following idea: If the evaluation of a term completes normally (no abruption (exception, break, continue, return) appeared) , the set of local variables calculated by the analysis is a subset of the variables that were actually assigned during evaluation.

To get more precise information about the sets of assigned variables the analysis includes the following optimisations:

- Inside of a while loop we also take care of the variables assigned before break statements, since the break causes the while loop to continue normally.
- For conditional statements we take care of constant conditions to statically determine the path of evaluation.
- Inside a distinct path of a conditional statements we know to which boolean value the condition has evaluated to, and so can retrieve more information about the variables assigned during evaluation of the boolean condition.

Since in our model of Java the return values of methods are stored in a local variable we also ensure that every path of (normal) evaluation will assign the result variable, or in the sense of real Java every path ends up in and return instruction.

Not covered yet:

- analysis of definite unassigned
- special treatment of final fields

Correct nesting of jump statements

For definite assignment it becomes crucial, that jumps (break, continue, return) are nested correctly i.e. a continue jump is nested in a matching while statement, a break jump is nested in a proper label statement, a class initialiser does not terminate abruptly with a return. With this we can for example ensure that evaluation of an expression will never end up with a jump, since no breaks, continues or returns are allowed in an expression.

The rules of definite assignment

types *breakass* = (*label*, *lname*) *tables*
— Mapping from a break label, to the set of variables that will be assigned if the evaluation terminates with this break

record *assigned* =
nrm :: *lname set* — Definetly assigned variables for normal completion
brk :: *breakass* — Definetly assigned variables for abrupt completion with a break

definition *rmlab* :: *'a* ⇒ (*'a*,*'b*) *tables* ⇒ (*'a*,*'b*) *tables* **where**
rmlab k A ≡ λ *x*. *if x=k then UNIV else A x*

definition *range-inter-ts* :: (*'a*,*'b*) *tables* ⇒ *'b set* (⇒⋂ - *80*) **where**
$\Rightarrow\bigcap A \equiv \{x\ |x.\ \forall\ k.\ x \in A\ k\}$

In $E \vdash B \gg t \gg A$, B denotes the "assigned" variables before evaluating term t, whereas A denotes the "assigned" variables after evaluating term t. The environment E is only needed for the conditional - *?* - : -. The definite assignment rules refer to the typing rules here to distinguish boolean and other expressions.

inductive

da :: *env* ⇒ *lname set* ⇒ *term* ⇒ *assigned* ⇒ *bool* (-⊢ - »-» - [*65*,*65*,*65*,*65*] *71*)
where
Skip: *Env*⊢ *B* »⟨*Skip*⟩» (⦇*nrm*=*B*,*brk*=λ *l*. *UNIV*⦈)

| *Expr*: *Env*⊢ *B* »⟨*e*⟩» *A*
⟹
Env⊢ *B* »⟨*Expr e*⟩» *A*
| *Lab*: ⟦*Env*⊢ *B* »⟨*c*⟩» *C*; *nrm A* = *nrm C* ∩ (*brk C*) *l*; *brk A* = *rmlab l* (*brk C*)⟧
⟹
Env⊢ *B* »⟨*Break l*• *c*⟩» *A*

| *Comp*: ⟦*Env*⊢ *B* »⟨*c1*⟩» *C1*; *Env*⊢ *nrm C1* »⟨*c2*⟩» *C2*;
nrm A = *nrm C2*; *brk A* = (*brk C1*) ⇒∩ (*brk C2*)⟧
⟹
Env⊢ *B* »⟨*c1*;; *c2*⟩» *A*

| *If*: ⟦*Env*⊢ *B* »⟨*e*⟩» *E*;
Env⊢ (*B* ∪ *assigns-if True e*) »⟨*c1*⟩» *C1*;
Env⊢ (*B* ∪ *assigns-if False e*) »⟨*c2*⟩» *C2*;
nrm A = *nrm C1* ∩ *nrm C2*;
brk A = *brk C1* ⇒∩ *brk C2* ⟧
⟹
Env⊢ *B* »⟨*If*(*e*) *c1 Else c2*⟩» *A*

— Note that *E* is not further used, because we take the specialized sets that also consider if the expression evaluates to true or false. Inside of *e* there is no `break` or `finally`, so the break map of *E* will be the trivial one. So *Env*⊢ *B* »⟨*e*⟩» *E* is just used to ensure the definite assignment in expression *e*. Notice the implicit analysis of a constant boolean expression *e* in this rule. For example, if *e* is constantly *True* then *assigns-if False e* = *UNIV* and therefor *nrm C2* = *UNIV*. So finally *nrm A* = *nrm C1*. For the break maps this trick workd too, because the trival break map will map all labels to *UNIV*. In the example, if no break occurs in *c2* the break maps will trivially map to *UNIV* and if a break occurs it will map to *UNIV* too, because *assigns-if False e* = *UNIV*. So in the intersection of the break maps the path *c2* will have no contribution.

| *Loop*: ⟦*Env*⊢ *B* »⟨*e*⟩» *E*;
Env⊢ (*B* ∪ *assigns-if True e*) »⟨*c*⟩» *C*;
nrm A = *nrm C* ∩ (*B* ∪ *assigns-if False e*);
brk A = *brk C*⟧
⟹
Env⊢ *B* »⟨*l*• *While*(*e*) *c*⟩» *A*
— The *Loop* rule resembles some of the ideas of the *If* rule. For the *nrm A* the set *B* ∪ *assigns-if False e* will be *UNIV* if the condition is constantly true. To normally exit the while loop, we must consider the body *c* to be completed normally (*nrm C*) or with a break. But in this model, the label *l* of the loop only handles continue labels, not break labels. The break label will be handled by an enclosing *Lab* statement. So we don't have to handle the breaks specially.

| *Jmp*: ⟦*jump*=*Ret* ⟶ *Result* ∈ *B*;
nrm A = *UNIV*;
brk A = (*case jump of*
Break l ⇒ λ *k*. *if k*=*l then B else UNIV*
| *Cont l* ⇒ λ *k*. *UNIV*
| *Ret* ⇒ λ *k*. *UNIV*)⟧
⟹
Env⊢ *B* »⟨*Jmp jump*⟩» *A*
— In case of a break to label *l* the corresponding break set is all variables assigned before the break. The assigned variables for normal completion of the *Jmp* is *UNIV*, because the statement will never complete normally. For continue and return the break map is the trivial one. In case of a return we enshure that the result value is assigned.

| *Throw*: ⟦*Env*⊢ *B* »⟨*e*⟩» *E*; *nrm A* = *UNIV*; *brk A* = (λ *l*. *UNIV*)⟧

$\Longrightarrow Env\vdash B \gg\langle Throw\ e\rangle\gg A$

| *Try*: $[\![Env\vdash B \gg\langle c1\rangle\gg C1;$
$Env(\!|lcl := lcl\ Env(VName\ vn\mapsto Class\ C)|\!)\vdash (B \cup \{VName\ vn\}) \gg\langle c2\rangle\gg C2;$
$nrm\ A = nrm\ C1 \cap nrm\ C2;$
$brk\ A = brk\ C1 \Rightarrow\cap\ brk\ C2]\!]$
$\Longrightarrow Env\vdash B \gg\langle Try\ c1\ Catch(C\ vn)\ c2\rangle\gg A$

| *Fin*: $[\![Env\vdash B \gg\langle c1\rangle\gg C1;$
$Env\vdash B \gg\langle c2\rangle\gg C2;$
$nrm\ A = nrm\ C1 \cup nrm\ C2;$
$brk\ A = ((brk\ C1) \Rightarrow\cup_\forall\ (nrm\ C2)) \Rightarrow\cap\ (brk\ C2)]\!]$
$\Longrightarrow$
$Env\vdash B \gg\langle c1\ Finally\ c2\rangle\gg A$

— The set of assigned variables before execution *c2* are the same as before execution *c1*, because *c1* could throw an exception and so we can't guarantee that any variable will be assigned in *c1*. The *Finally* statement completes normally if both *c1* and *c2* complete normally. If *c1* completes abruptly with a break, then *c2* also will be executed and may terminate normally or with a break. The overall break map then is the intersection of the maps of both paths. If *c2* terminates normally we have to extend all break sets in *brk C1* with *nrm C2* ($\Rightarrow\cup_\forall$). If *c2* exits with a break this break will appear in the overall result state. We don't know if *c1* completed normally or abruptly (maybe with an exception not only a break) so *c1* has no contribution to the break map following this path.

— Evaluation of expressions and the break sets of definite assignment: Thinking of a Java expression we assume that we can never have a break statement inside of a expression. So for all expressions the break sets could be set to the trivial one: $\lambda l.\ UNIV$. But we can't trivially proof, that evaluating an expression will never result in a break, allthough Java expressions allready syntactically don't allow nested stetements in them. The reason are the nested class initialzation statements which are inserted by the evaluation rules. So to proof the absence of a break we need to ensure, that the initialization statements will never end up in a break. In a wellfromed initialization statement, of course, were breaks are nested correctly inside of *Lab* or *Loop* statements evaluation of the whole initialization statement will never result in a break, because this break will be handled inside of the statement. But for simplicity we haven't added the analysis of the correct nesting of breaks in the typing judgments right now. So we have decided to adjust the rules of definite assignment to fit to these circumstances. If an initialization is involved during evaluation of the expression (evaluation rules *FVar*, *NewC* and *NewA*

| *Init*: $Env\vdash B \gg\langle Init\ C\rangle\gg (\!|nrm{=}B,brk{=}\lambda\ l.\ UNIV|\!)$
— Wellformedness of a program will ensure, that every static initialiser is definetly assigned and the jumps are nested correctly. The case here for *Init* is just for convenience, to get a proper precondition for the induction hypothesis in various proofs, so that we don't have to expand the initialisation on every point where it is triggerred by the evaluation rules.
| *NewC*: $Env\vdash B \gg\langle NewC\ C\rangle\gg (\!|nrm{=}B,brk{=}\lambda\ l.\ UNIV|\!)$

$\Longrightarrow$
$Env\vdash\ B \gg\langle c\ ?\ e1\ :\ e2\rangle\gg\ A$

| *Call*: $\llbracket Env\vdash\ B \gg\langle e\rangle\gg\ E;\ Env\vdash\ nrm\ E \gg\langle args\rangle\gg\ A\rrbracket$
$\Longrightarrow$
$Env\vdash\ B \gg\langle\{accC,statT,mode\}e{\cdot}mn(\{pTs\}args)\rangle\gg\ A$

— The interplay of *Call*, *Methd* and *Body*: Why rules for *Methd* and *Body* at all? Note that a Java source program will not include bare *Methd* or *Body* terms. These terms are just introduced during evaluation. So definite assignment of *Call* does not consider *Methd* or *Body* at all. So for definite assignment alone we could omit the rules for *Methd* and *Body*. But since evaluation of the method invocation is split up into three rules we must ensure that we have enough information about the call even in the *Body* term to make sure that we can proof type safety. Also we must be able transport this information from *Call* to *Methd* and then further to *Body* during evaluation to establish the definite assignment of *Methd* during evaluation of *Call*, and of *Body* during evaluation of *Methd*. This is necessary since definite assignment will be a precondition for each induction hypothesis coming out of the evaluation rules, and therefor we have to establish the definite assignment of the sub-evaluation during the type-safety proof. Note that well-typedness is also a precondition for type-safety and so we can omit some assertion that are already ensured by well-typedness.
| *Methd*: $\llbracket methd\ (prg\ Env)\ D\ sig = Some\ m;$
$Env\vdash\ B \gg\langle Body\ (declclass\ m)\ (stmt\ (mbody\ (mthd\ m)))\rangle\gg\ A$
$\rrbracket$
$\Longrightarrow$
$Env\vdash\ B \gg\langle Methd\ D\ sig\rangle\gg\ A$

| *Body*: $\llbracket Env\vdash\ B \gg\langle c\rangle\gg\ C;\ jumpNestingOkS\ \{Ret\}\ c;\ Result \in nrm\ C;$
$nrm\ A = B;\ brk\ A = (\lambda\ l.\ UNIV)\rrbracket$
$\Longrightarrow$
$Env\vdash\ B \gg\langle Body\ D\ c\rangle\gg\ A$
— Note that A is not correlated to C. If the body statement returns abruptly with return, evaluation of *Body* will absorb this return and complete normally. So we cannot trivially get the assigned variables of the body statement since it has not completed normally or with a break. If the body completes normally we guarantee that the result variable is set with this rule. But if the body completes abruptly with a return we can't guarantee that the result variable is set here, since definite assignment only talks about normal completion and breaks. So for a return the *Jump* rule ensures that the result variable is set and then this information must be carried over to the *Body* rule by the conformance predicate of the state.

Chapter 13

WellForm

34 Well-formedness of Java programs

theory *WellForm* **imports** *DefiniteAssignment* **begin**

For static checks on expressions and statements, see WellType.thy
improvements over Java Specification 1.0 (cf. 8.4.6.3, 8.4.6.4, 9.4.1):

- a method implementing or overwriting another method may have a result type that widens to the result type of the other method (instead of identical type)
- if a method hides another method (both methods have to be static!) there are no restrictions to the result type since the methods have to be static and there is no dynamic binding of static methods
- if an interface inherits more than one method with the same signature, the methods need not have identical return types

simplifications:

- Object and standard exceptions are assumed to be declared like normal classes

well-formed field declarations

well-formed field declaration (common part for classes and interfaces), cf. 8.3 and (9.3)

definition *wf-fdecl* :: *prog* ⇒ *pname* ⇒ *fdecl* ⇒ *bool* **where**
wf-fdecl G P ≡ λ(*fn*,*f*). *is-acc-type G P* (*type f*)

lemma *wf-fdecl-def2*: ⋀*fd*. *wf-fdecl G P fd* = *is-acc-type G P* (*type* (*snd fd*))
⟨*proof*⟩

well-formed method declarations

A method head is wellformed if:

- the signature and the method head agree in the number of parameters
- all types of the parameters are visible
- the result type is visible
- the parameter names are unique

definition *wf-mhead* :: *prog* ⇒ *pname* ⇒ *sig* ⇒ *mhead* ⇒ *bool* **where**
wf-mhead G P ≡ λ *sig mh*. *length* (*parTs sig*) = *length* (*pars mh*) ∧
(∀ *T*∈*set* (*parTs sig*). *is-acc-type G P T*) ∧
is-acc-type G P (*resTy mh*) ∧
distinct (*pars mh*)

A method declaration is wellformed if:

- the method head is wellformed
- the names of the local variables are unique
- the types of the local variables must be accessible
- the local variables don't shadow the parameters

- the class of the method is defined
- the body statement is welltyped with respect to the modified environment of local names, were the local variables, the parameters the special result variable (Res) and This are assoziated with there types.

well-formed interface declarations

A interface declaration is wellformed if:

- the interface hierarchy is wellstructured
- there is no class with the same name
- the method heads are wellformed and not static and have Public access
- the methods are uniquely named
- all superinterfaces are accessible
- the result type of a method overriding a method of Object widens to the result type of the overridden method. Shadowing static methods is forbidden.
- the result type of a method overriding a set of methods defined in the superinterfaces widens to each of the corresponding result types

⟨*proof*⟩

well-formed class declarations

A class declaration is wellformed if:

- there is no interface with the same name
- all superinterfaces are accessible and for all methods implementing an interface method the result type widens to the result type of the interface method, the method is not static and offers at least as much access (this actually means that the method has Public access, since all interface methods have public access)
- all field declarations are wellformed and the field names are unique
- all method declarations are wellformed and the method names are unique
- the initialization statement is welltyped
- the classhierarchy is wellstructured
- Unless the class is Object:
  - the superclass is accessible
  - for all methods overriding another method (of a superclass)the result type widens to the result type of the overridden method, the access modifier of the new method provides at least as much access as the overwritten one.
  - for all methods hiding a method (of a superclass) the hidden method must be static and offer at least as much access rights. Remark: In contrast to the Java Language Specification we don't restrict the result types of the method (as in case of overriding), because there seems to be no reason, since there is no dynamic binding of static methods. (cf. 8.4.6.3 vs. 15.12.1). Stricly speaking the restrictions on the access rights aren't necessary to, since the static type and the access rights together determine which method is to be called statically. But if a class gains more then one static method with the same signature due to inheritance, it is confusing when the method selection depends on the access rights only: e.g. Class C declares static public method foo(). Class D is subclass of C and declares static method foo() with default package access. D.foo() ? if this call is in the same package as D then foo of class D is called, otherwise foo of class C.

definition *entails* :: ('*a*,'*b*) *table* ⇒ ('*b* ⇒ *bool*) ⇒ *bool* (- *entails* - *20*) **where**

well-formed programs

A program declaration is wellformed if:

- the class ObjectC of Object is defined
- every method of Object has an access modifier distinct from Package. This is necessary since every interface automatically inherits from Object. We must know, that every time a Object method is "overriden" by an interface method this is also overriden by the class implementing the the interface (see *implement-dynmethd and class-mheadsD*)
- all standard Exceptions are defined
- all defined interfaces are wellformed
- all defined classes are wellformed

Compare this lemma about static overriding $G \vdash new\ overrides_S\ old$ with the definition of dynamic overriding $G \vdash new\ overrides\ old$. Conforming result types and restrictions on the access modifiers of the old and the new method are not part of the predicate for static overriding. But they are enshured in a wellfromed program. Dynamic overriding has no restrictions on the access modifiers but enforces confrom result types as precondition. But with some efford we can guarantee the access modifier restriction for dynamic overriding, too. See lemma *wf-prog-dyn-override-prop*.

Which dynamic classes are valid to look up a member of a distinct static type? We have to distinct class members (named static members in Java) from instance members. Class members are global to all Objects of a class, instance members are local to a single Object instance. If a member is equipped with the static modifier it is a class member, else it is an instance member. The following table gives an overview of the current framework. We assume to have a reference with static type statT and a dynamic class dynC. Between both of these types the widening relation holds *G⊢Class dynC⪯statT*. Unfortunately this ordinary widening relation isn't enough to describe the valid lookup classes, since we must cope the special cases of arrays and interfaces,too. If we statically expect an array or inteface we may lookup a field or a method in Object which isn't covered in the widening relation.

statT field instance method static (class) method ——————————————————————————— NullT / / / Iface / dynC Object Class dynC dynC dynC Array / Object Object

In most cases we con lookup the member in the dynamic class. But as an interface can't declare new static methods, nor an array can define new methods at all, we have to lookup methods in the base class Object.

The limitation to classes in the field column is artificial and comes out of the typing rule for the field access (see rule *FVar* in the welltyping relation *wt* in theory WellType). I stems out of the fact, that Object indeed has no non private fields. So interfaces and arrays can actually have no fields at all and a field access would be senseless. (In Java interfaces are allowed to declare new fields but in current Bali not!). So there is no principal reason why we should not allow Objects to declare non private fields. Then we would get the following column:

statT field ——————— NullT / Iface Object Class dynC Array Object

State

36 State for evaluation of Java expressions and statements

theory *State*
imports *DeclConcepts*
begin

design issues:

- all kinds of objects (class instances, arrays, and class objects) are handeled via a general object abstraction
- the heap and the map for class objects are combined into a single table (*recall* (*loc*, *obj*) *table* × (*qtname*, *obj*) *table* ~= (*loc* + *qtname*, *obj*) *table*)

objects

datatype *obj-tag* = — tag for generic object
CInst qtname — class instance
| *Arr ty int* — array with component type and length
— — CStat qtname the tag is irrelevant for a class object, i.e. the static fields of a class, since its type is given already by the reference to it (see below)

types *vn* = *fspec* + *int* — variable name
record *obj* =
tag :: *obj-tag* — generalized object
values :: (*vn*, *val*) *table*

translations

Chapter 15

Eval

42 Operational evaluation (big-step) semantics of Java expressions and statements

theory *Eval* **imports** *State DeclConcepts* **begin**

improvements over Java Specification 1.0:

- dynamic method lookup does not need to consider the return type (cf.15.11.4.4)
- throw raises a NullPointer exception if a null reference is given, and each throw of a standard exception yield a fresh exception object (was not specified)
- if there is not enough memory even to allocate an OutOfMemory exception, evaluation/execution fails, i.e. simply stops (was not specified)
- array assignment checks lhs (and may throw exceptions) before evaluating rhs
- fixed exact positions of class initializations (immediate at first active use)

design issues:

- evaluation vs. (single-step) transition semantics evaluation semantics chosen, because:
  - ++ less verbose and therefore easier to read (and to handle in proofs)
  - + more abstract
  - + intermediate values (appearing in recursive rules) need not be stored explicitly, e.g. no call body construct or stack of invocation frames containing local variables and return addresses for method calls needed
  - + convenient rule induction for subject reduction theorem
  - - no interleaving (for parallelism) can be described
  - - stating a property of infinite executions requires the meta-level argument that this property holds for any finite prefixes of it (e.g. stopped using a counter that is decremented to zero and then throwing an exception)
- unified evaluation for variables, expressions, expression lists, statements
- the value entry in statement rules is redundant
- the value entry in rules is irrelevant in case of exceptions, but its full inclusion helps to make the rule structure independent of exception occurence.
- as irrelevant value entries are ignored, it does not matter if they are unique. For simplicity, (fixed) arbitrary values are preferred over "free" values.
- the rule format is such that the start state may contain an exception.
  - ++ faciliates exception handling
  - + symmetry
- the rules are defined carefully in order to be applicable even in not type-correct situations (yielding undefined values), e.g. *the-Addr* (*Val* (*Bool b*)) = *undefined*.
  - ++ fewer rules
  - - less readable because of auxiliary functions like *the-Addr*

  Alternative: "defensive" evaluation throwing some InternalError exception in case of (impossible, for correct programs) type mismatches

- there is exactly one rule per syntactic construct

  \+ no redundancy in case distinctions

- halloc fails iff there is no free heap address. When there is only one free heap address left, it returns an OutOfMemory exception. In this way it is guaranteed that when an OutOfMemory exception is thrown for the first time, there is a free location on the heap to allocate it.

- the allocation of objects that represent standard exceptions is deferred until execution of any enclosing catch clause, which is transparent to the program.

  \- requires an auxiliary execution relation

  ++ avoids copies of allocation code and awkward case distinctions (whether there is enough memory to allocate the exception) in evaluation rules

- unfortunately *new-Addr* is not directly executable because of Hilbert operator.

simplifications:

- local variables are initialized with default values (no definite assignment)
- garbage collection not considered, therefore also no finalizers
- stack overflow and memory overflow during class initialization not modelled
- exceptions in initializations not replaced by ExceptionInInitializerError

types *vvar* = *val* × (*val* ⇒ *state* ⇒ *state*)
vals = (*val*, *vvar*, *val list*) *sum3*
translations
(*type*) *vvar* <= (*type*) *val* × (*val* ⇒ *state* ⇒ *state*)
(*type*) *vals* <= (*type*) (*val*, *vvar*, *val list*) *sum3*

To avoid redundancy and to reduce the number of rules, there is only one evaluation rule for each syntactic term. This is also true for variables (e.g. see the rules below for *LVar*, *FVar* and *AVar*). So evaluation of a variable must capture both possible further uses: read (rule *Acc*) or write (rule *Ass*) to the variable. Therefor a variable evaluates to a special value *vvar*, which is a pair, consisting of the current value (for later read access) and an update function (for later write access). Because during assignment to an array variable an exception may occur if the types don't match, the update function is very generic: it transforms the full state. This generic update function causes some technical trouble during some proofs (e.g. type safety, correctness of definite assignment). There we need to prove some additional invariant on this update function to prove the assignment correct, since the update function could potentially alter the whole state in an arbitrary manner. This invariant must be carried around through the whole induction. So for future approaches it may be better not to take such a generic update function, but only to store the address and the kind of variable (array (+ element type), local variable or field) for later assignment.

— This class initialisation rule is a little bit inaccurate. Look at the exact sequence: (1) The current class object (the static fields) are initialised (*init-class-obj*), (2) the superclasses are initialised, (3) the static initialiser of the current class is invoked. More precisely we should expect another ordering, namely 2 1 3. But we can't just naively toggle 1 and 2. By calling *init-class-obj* before initialising the superclasses, we also implicitly record that we have started to initialise the current class (by setting an value for the class object). This becomes crucial for the completeness proof of the axiomatic semantics *AxCompl.thy*. Static initialisation requires an induction on the number of classes not yet initialised (or to be more precise, classes were the initialisation has not yet begun). So we could first assign a dummy value to the class before superclass initialisation and afterwards set the correct values. But as long as we don't take memory overflow into account when allocating class objects, we can leave things as they are for convenience.

— The interplay of *Call*, *Methd* and *Body*: Method invocation is split up into these three rules:

Call Calculates the target address and evaluates the arguments of the method, and then performs dynamic or static lookup of the method, corresponding to the call mode. Then the *Methd* rule is evaluated on the calculated declaration class of the method invocation.

Methd A syntactic bridge for the folded method body. It is used by the axiomatic semantics to add the proper hypothesis for recursive calls of the method.

Body An extra syntactic entity for the unfolded method body was introduced to properly trigger class ini-

tialisation. Without class initialisation we could just evaluate the body statement.

Chapter 16

Example

43 Example Bali program

theory *Example*
imports *Eval WellForm*
begin

The following example Bali program includes:

- class and interface declarations with inheritance, hiding of fields, overriding of methods (with refined result type), array type,
- method call (with dynamic binding), parameter access, return expressions,
- expression statements, sequential composition, literal values, local assignment, local access, field assignment, type cast,
- exception generation and propagation, try and catch statement, throw statement
- instance creation and (default) static initialization

```
package java_lang

public interface HasFoo {
  public Base foo(Base z);
}

public class Base implements HasFoo {
  static boolean arr[] = new boolean[2];
  public HasFoo vee;
  public Base foo(Base z) {
    return z;
  }
}

public class Ext extends Base {
  public int vee;
  public Ext foo(Base z) {
    ((Ext)z).vee = 1;
    return null;
  }
}

public class Main {
  public static void main(String args[]) throws Throwable {
    Base e = new Ext();
    try {e.foo(null); }
    catch(NullPointerException z) {
      while(Ext.arr[2]) ;
    }
  }
}
```

Conform

44 Conformance notions for the type soundness proof for Java

theory *Conform* **imports** *State* **begin**

design issues:

- lconf allows for (arbitrary) inaccessible values
- "conforms" does not directly imply that the dynamic types of all objects on the heap are indeed existing classes. Yet this can be inferred for all referenced objs.

types *env'* = *prog* × (*lname*, *ty*) *table*

extension of global store

definition *gext* :: *st* ⇒ *st* ⇒ *bool* (-≤|- [*71*,*71*] *70*) **where**
s≤|*s'* ≡ ∀ *r*. ∀ *obj*∈*globs s r*: ∃ *obj'*∈*globs s' r*: *tag obj'*= *tag obj*

For the the proof of type soundness we will need the property that during execution, objects are not lost and moreover retain the values of their tags. So the object store grows conservatively. Note that if we considered garbage collection, we would have to restrict this property to accessible objects.

lemma *gext-objD*:

⟨*proof*⟩

weak value list conformance

Only if the value is defined it has to conform to its type. This is the contribution of the definite assignment analysis to the notion of conformance. The definite assignment analysis ensures that the program only attempts to access local variables that actually have a defined value in the state. So conformance must only ensure that the defined values are of the right type, and not also that the value is defined.

definition *wlconf* :: *prog* ⇒ *st* ⇒ (*'a*, *val*) *table* ⇒ (*'a*, *ty*) *table* ⇒ *bool* (-,-⊢-[∼::≼]- [*71*,*71*,*71*,*71*] *70*)

The next theorem expresses: If jumps (breaks, continues, returns) are nested correctly, we won't find an unexpected jump in the result state of the evaluation. For exeample, a break can't leave its enclosing loop, an return cant leave its enclosing method. To proove this, the method call is critical. Allthough the wellformedness of the whole program guarantees that the jumps (breaks,continues and returns) are nested correctly in all method bodies, the call rule alone does not guarantee that I will call a method or even a class that is part of the program due to dynamic binding! To be able to enshure this we need a kind of conformance of the state, like in the typesafety proof. But then we will redo the typesafty proof here. It would be nice if we could find an easy precondition that will guarantee that all calls will actually call classes and methods of the current program, which can be instantiated in the typesafty proof later on. To fix this problem, I have instrumented the semantic definition of a call to filter out any breaks in the state and to throw an error instead.

To get an induction hypothesis which is strong enough to perform the proof, we can't just assume *jumpNestingOk* for the empty set and conlcude, that no jump at all will be in the resulting state, because the set is altered by the statements *Lab* and *While*.

The wellformedness of the program is used to enshure that for all classinitialisations and methods the nesting of jumps is wellformed, too.

⟨*proof*⟩

Since assignments are modelled as functions from states to states, we must take into account these functions. They appear only in the assignment rule and as result from evaluating a variable. Thats why we need the complicated second part of the conjunction in the goal. The reason for the very generic way to treat assignments was the aim to omit redundancy. There is only one evaluation rule for each kind of variable (locals, fields, arrays). These rules are used for both accessing variables and updating variables. Thats why the evaluation rules for variables result in a pair consisting of a value and an update function. Of course we could also think of a pair of a value and a reference in the store, instead of the generic update function. But as only array updates can cause a special exception (if the types mismatch) and not array reads we then have to introduce two different rules to handle array reads and updates

$(\forall\, s'\ w.\ \mathit{error\text{-}free}\ s' \longrightarrow (\mathit{error\text{-}free}\ (\mathit{assign}\ f\ w\ s')))$

definition *rconf* :: *prog* ⇒ *lenv* ⇒ *st* ⇒ *term* ⇒ *vals* ⇒ *tys* ⇒ *bool* (-,-,-⊢-≻-::≼- [71,71,71,71,71,71] 70) **where**

```
G,L,s⊢t≻v::≼T
 ≡ case T of
     Inl T ⇒ if (∃ var. t=In2 var)
               then (∀ n. (the-In2 t) = LVar n
                      ⟶ (fst (the-In2 v) = the (locals s n)) ∧
                          (locals s n ≠ None ⟶ G,s⊢fst (the-In2 v)::≼T)) ∧
                    (¬ (∃ n. the-In2 t=LVar n) ⟶ (G,s⊢fst (the-In2 v)::≼T))∧
                    (s≤|snd (the-In2 v)≼T::≼(G,L))
               else G,s⊢the-In1 v::≼T
   | Inr Ts ⇒ list-all2 (conf G s) (the-In3 v) Ts
```

With *rconf* we describe the conformance of the result value of a term. This definition gets rather complicated because of the relations between the injections of the different terms, types and values. The main case distinction is between single values and value lists. In case of value lists, every value has to conform to its type. For single values we have to do a further case distinction, between values of variables $\exists\, var.\ t = In2\ var$ and ordinary values. Values of variables are modelled as pairs consisting of the current value and an update function which will perform an assignment to the variable. This stems form the decision, that we only have one evaluation rule for each kind of variable. The decision if we read or write to the variable is made by syntactic enclosing rules. So conformance of variable-values must ensure that both the current value and an update will conform to the type. With the introduction of definite assignment of local variables we have to do another case distinction. For the notion of conformance local variables are allowed to be *None*, since the definedness is not ensured by conformance but by definite assignment. Field and array variables must contain a value.

48 Ideas for the future

In the type soundness proof and the correctness proof of definite assignment we perform induction on the evaluation relation with the further preconditions that the term is welltyped and definitely assigned. During the proofs we have to establish the welltypedness and definite assignment of the subterms to be able to apply the induction hypothesis. So large parts of both proofs are the same work in propagating welltypedness and definite assignment. So we can derive a new induction rule for induction on the evaluation of a wellformed term, were these propagations is already done, once and forever. Then we can do the proofs with this rule and can enjoy the time we have saved. Here is a first and incomplete sketch of such a rule.

theorem *wellformed-eval-induct* [*consumes 4*, *case-names Abrupt Skip Expr Lab Comp If*]:
assumes *eval*: $G⊢s0\ -t≻→\ (v,s1)$

Chapter 20

Evaln

49 Operational evaluation (big-step) semantics of Java expressions and statements

theory *Evaln* **imports** *TypeSafe* **begin**

Variant of *eval* relation with counter for bounded recursive depth. In principal *evaln* could replace *eval*.

Validity of the axiomatic semantics builds on *evaln*. For recursive method calls the axiomatic semantics rule assumes the method ok to derive a proof for the body. To prove the method rule sound we need to perform induction on the recursion depth. For the completeness proof of the axiomatic semantics the notion of the most general formula is used. The most general formula right now builds on the ordinary evaluation relation *eval*. So sometimes we have to switch between *evaln* and *eval* and vice versa. To make this switch easy *evaln* also does all the technical accessibility tests *check-field-access* and *check-method-access* like *eval*. If it would omit them *evaln* and *eval* would only be equivalent for welltyped, and definitely assigned terms.

inductive

— Notice, that we do not have literal values for *vars*. The rules for accessing variables (*Acc*) and assigning to variables (*Ass*), test this with the predicate *groundVar*. After initialisation is done and the *FVar* is evaluated, we can't just throw away the *InsInitFVar* term and return a literal value, as in the cases of *New* or *NewC*. Instead we just return the evaluated *FVar* and test for initialisation in the rule *FVar*.

Chapter 22

AxSem

50 Axiomatic semantics of Java expressions and statements (see also Eval.thy)

theory *AxSem* **imports** *Evaln TypeSafe* **begin**

design issues:

- a strong version of validity for triples with premises, namely one that takes the recursive depth needed to complete execution, enables correctness proof
- auxiliary variables are handled first-class (-¿ Thomas Kleymann)
- expressions not flattened to elementary assignments (as usual for axiomatic semantics) but treated first-class =¿ explicit result value handling
- intermediate values not on triple, but on assertion level (with result entry)
- multiple results with semantical substitution mechnism not requiring a stack
- because of dynamic method binding, terms need to be dependent on state. this is also useful for conditional expressions and statements
- result values in triples exactly as in eval relation (also for xcpt states)
- validity: additional assumption of state conformance and well-typedness, which is required for soundness and thus rule hazard required of completeness

restrictions:

- all triples in a derivation are of the same type (due to weak polymorphism)

rules derived from conseq

In the following rules we often have to give some type annotations like: $G,A\vdash\{P\}\ t\succ\ \{Q\}$. Given only the term above without annotations, Isabelle would infer a more general type were we could have different types of auxiliary variables in the assumption set (A) and in the triple itself (P and Q). But *ax-derivs.Methd* enforces the same type in the inductive definition of the derivation. So we have to restrict the types to be able to apply the rules.

Chapter 23

AxSound

62 Soundness proof for Axiomatic semantics of Java expressions and statements

theory *AxSound* **imports** *AxSem* **begin**

validity

consts

$$\begin{array}{l} \textit{triple-valid2}:: \textit{prog} \Rightarrow \textit{nat} \Rightarrow \quad 'a\ \textit{triple} \Rightarrow \textit{bool} \\ \qquad\qquad\qquad\qquad\qquad\qquad (\quad \text{-}\models\text{-::-}[61,0,\ 58]\ 57) \\ \quad \textit{ax-valids2}:: \textit{prog} \Rightarrow 'a\ \textit{triples} \Rightarrow 'a\ \textit{triples} \Rightarrow \textit{bool} \\ \qquad\qquad\qquad\qquad\qquad\qquad (\text{-,-}|\models\text{::-}\ [61,58,58]\ 57) \end{array}$$

defs *triple-valid2-def*: $G\models n::t \equiv \textit{case}\ t\ \textit{of}\ \{P\}\ t\succ\ \{Q\} \Rightarrow$
$\forall\ Y\ s\ Z.\ P\ Y\ s\ Z \longrightarrow (\forall\ L.\ s::\preceq(G,L)$
$\longrightarrow (\forall\ T\ C\ A.\ (\textit{normal}\ s \longrightarrow ((\!|prg=G,cls=C,lcl=L|\!)\vdash t::T\ \wedge$
$\qquad (\!|prg=G,cls=C,lcl=L|\!)\vdash \textit{dom}\ (\textit{locals}\ (\textit{store}\ s))\gg t\gg A)) \longrightarrow$
$(\forall\ Y'\ s'.\ G\vdash s\ -t\succ -n\rightarrow\ (Y',s') \longrightarrow Q\ Y'\ s'\ Z\ \wedge\ s'::\preceq(G,L))))$

This definition differs from the ordinary *triple-valid-def* manly in the conclusion: We also ensures conformance of the result state. So we don't have to apply the type soundness lemma all the time during induction. This definition is only introduced for the soundness proof of the axiomatic semantics, in the end we will conclude to the ordinary definition.
